# PALEY'S NATURAL THEOLOGY.

*REVISED TO HARMONIZE WITH MODERN SCIENCE*

BY

F. LE GROS CLARK, F.R.S.

FORMERLY PRESIDENT AND HUNTERIAN PROFESSOR OF SURGERY AND  
PATHOLOGY IN THE ROYAL COLLEGE OF SURGEONS OF ENGLAND;  
CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL, ETC.

LONDON:

THE CHRISTIAN EVIDENCE COMMITTEE OF THE  
SOCIETY FOR PROMOTING CHRISTIAN KNOWLEDGE,  
NORTHUMBERLAND AVENUE, W.C.; 43, QUEEN VICTORIA STREET, E.C.

BRIGHTON: 129, NORTH STREET.

NEW YORK: E. & J. B. YOUNG & CO.

1902.

The Christian Evidence Committee of the S.P.C.K., whilst giving its general approval to the works of the Christian Evidence Series, does not hold itself responsible for every statement or every line of argument.

The responsibility of each writer extends to his own work only.

## PREFACE.

THE present edition of Paley's "Natural Theology" has been prepared at the request of the Society, the object proposed being an issue of this standard work, with such alterations in the illustrative part of the text as are required by the progress of science since the author's time. This remark will be found to apply chiefly to the anatomical and physiological illustrations, but not exclusively so. The natural history, in all its departments, has also been revised; indeed the revision has been extended throughout the volume. Yet care has been exercised not in any way to interfere with the general plan and argument of Paley, and to preserve his style and diction as much as possible: the deviations from the original text are such only as were rendered necessary to fulfil the condition on which the task was undertaken. This

has been accomplished by the omission or correction of errors, and by the substitution and addition of fresh illustrations where they appeared to be needed. It is hoped that the value of the work will be thereby enhanced, whilst its distinctive characteristics are retained without mutilation; and that the volume may be thus rendered more worthy of the high and just estimation in which it continues to be held. If the effort to accomplish this object be approved, less reserve may be exercised in a future edition, by drawing more liberally from the ever-expanding sphere of the physical sciences.

| The circulation of the blood ; its utility. Disposition of the blood-vessels ; arteries and veins. The heart ; its agency in the circulation. The lungs ; respiration ; its effect in purifying the blood. Valves in the heart and great arteries. Uses of the blood. Digestion of the food, and conveyance of nutriment into the circulation. Nature of digestion ; the gastric juice ; its action. The bile, gall-bladder and gall-duct. The saliva and salivary glands. The gullet and wind-pipe ; their relations and uses. Structure and uses of the larynx. Collective action and mutual subserviency of various parts of the frame . . . . . | 157 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

## CHAPTER XI.

## OF THE ANIMAL STRUCTURE REGARDED AS A MASS.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Correspondence of the two sides. Symmetry and resemblance of duplicate parts. Absence of symmetry within the chest and abdomen. Package and protection of the viscera and other parts. Beauty of form and colour, exemplified in plants and animals. The skins of animals. The active power by which the body is maintained in the erect posture. The bird on its perch. The membrane covering the bones. The scarf-skin. The skull as a protection to the brain . . . . . | PAGE<br>193 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|

## CHAPTER XII.

## COMPARATIVE ANATOMY.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |     |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| Varied covering of animals. Of man ; of birds ; structure of feathers. Various forms of mouth. The teeth, and their formation ; their structure in different classes of animals ; in man as a mixed feeder. The bills of birds. The gullet ; the stomach ; the intestines ; their adaptation to the habits of animals. Bones of quadrupeds ; of birds. The lungs of birds ; their peculiarity. Why birds are oviparous. Instruments of motion : wings of birds ; fins of fish ; web-feet of birds. The senses of different animals ; their relative development . . . | 217 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

## CHAPTER XIII.

## PECULIAR ORGANIZATIONS.

|                                                                                                 |  |
|-------------------------------------------------------------------------------------------------|--|
| Long necks of quadrupeds ; how supported. Whale-bone. Oily secretion of birds. Swimming-bladder |  |
|-------------------------------------------------------------------------------------------------|--|

---

|                                                                                                                                                             | PAGE |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| of fish. Poison-fangs of serpents. Bag of opossum.<br>Claws and bills of birds. Stomach of camel. Tongue<br>of woodpecker. Tusks of walrus. The sloth . . . | 254  |

## CHAPTER XIV.

### PROSPECTIVE CONTRIVANCES.

|                                                                                                                                                                     |     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| The teeth ; their development. Horns. Milk ; its secretion. The eye before birth. The lungs before birth. Structural arrangements peculiar to foetal life . . . . . | 269 |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

## CHAPTER XV.

### RELATIONS.

|                                                                                                                                                                                                                                                                                                                                                        |     |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| The fitness of parts to each other, illustrated by the structure of a watch ; exemplified in the animal economy. Digestion in different animals. The kidneys and bladder. Position of the eyes. The sexes. The teats and mouth. Particular relations. The swan's bill, neck, and stomach. Form and structure of the mole ; its feet, eyes, &c. . . . . | 279 |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

## CHAPTER XVI.

### COMPENSATION.

|                                                                                                                                                                                                                                                                                                                                                                                               |     |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| Proboscis of elephant. Hook on bat's wing. Legs and bill of crane. Tongues of birds. Spider's web. Multiple eyes of insects. The chameleon. The snail, mussel, and cockle. The lobster ; its growth and change of shell ; repair of injury. The sloth. The sheep. The clothing of animals. Ruminating animals. The bills and gizzards of birds. Locomotive organs of snakes and worms . . . . | 293 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

## CHAPTER XVII.

THE RELATION OF ANIMATED BODIES TO INANIMATE  
NATURE.

|                                                                                                                                                                                                                                                       | PAGE |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| Wings of birds. Fins of fish. The ear and the atmosphere. Organs of voice and respiration. Sight and light. Proportion in the size of animals. Earth and sea. The earth and its inhabitants. Sleep and night. Day and night. Hybernation. Migration . | 311  |

## CHAPTER XVIII.

## INSTINCTS.

|                                                                                                                                                                                                                                      |     |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| Definition. Incubation of eggs ; in birds. Instinct of oviparous economy in insects. Love of offspring. Spawning of fish. Attempts to explain maternal instincts. Building of nests. Hybernating animals. Pairing of birds . . . . . | 319 |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

## CHAPTER XIX.

## OF INSECTS.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| Structure of insects ; their legs ; their wings. The dragon-fly. The gnat ; its birth. Habits of insects. Their jaws or mandibles ; their palpi ; sucking mouth and proboscis. The stings of insects ; their structure and action. Feeding of the butterfly. Gizzard of insects.. Sense of touch in insects. Circulation and purification of the blood. Metamorphoses of insects. Security of their eggs. Poison-fang of spider. Spinning apparatus of caterpillar and spider. Bees. Production of wax and honey ; use of the sting. Stag-beetle. House-fly. Glow-worm. Electric organ of torpedo. Phosphorescence of sea. Mechanism of shells. Snails. Shell-fish. Bivalves. Lobster's shell and tail. Variety in nature ; in breathing-organs ; in clothing ; in appetites . . . | 340 |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

## CHAPTER XX.

## OF PLANTS.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | PAGE |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| Two-fold law of vegetation. Perfecting of the seed.<br>Structure of plants. Peculiarities adapted to utility.<br>Protection of buds; of seeds. Fruits; their uses: diverse kinds. Dispersion of seeds. Structure of seeds. Germination. Climbing plants; tendrils. Grasses; their variety and uses. Growth of vallisneria; of parasitical plants: the mistletoe. Compensation in plants. Protection of seeds and plants in winter. The dioncea; its structure and habits . | 369  |

## CHAPTER XXI.

## THE ATMOSPHERE, WATER, HEAT, AND LIGHT.

|                                                                                                                                                                                                                                                                                              |     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| The atmosphere; its various uses in supporting life, combustion, &c. Water; its qualities and uses. Relation of water to land. Heat; its sources and influence. Light; its rate of travelling; its properties; different lengths of the waves of light producing variety of colour . . . . . | 392 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

## CHAPTER XXII.

## ASTRONOMY.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| Movements of heavenly bodies. Extent of our astronomical knowledge. The sun the source of heat and light. Earth an oblate spheroid. Probable structure and density of the earth. Geological investigation, and conclusions drawn therefrom. Centripetal forces and <i>vis inertiae</i> . Attraction. Perturbations. Movements of the planets. Origin of our planetary system. Motion of the moon. Law of gravitation not a blind impulse . . . . | 400 |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

### CHAPTER XXIII.

#### OF THE PERSONALITY OF THE DEITY.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <small>PAGE</small> |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| Contrivance proves personality. Definition of personality. Attributes of the Deity. Our means of becoming acquainted with the Divine essence. Contrivance and intelligence. Definition of law. Difference between mechanism and power. Illustration by movements and works of a watch. Second Causes. Principles in relation to phenomena. Generation not a principle, but a process. Relations of air to lungs, and of light to the eye. Unconscious energies. Buffon's organic molecules. Internal moulds, and appetencies. Development from use or accident. Objections to these theories; exemplified especially by the senses . . . . . | 420                 |

### CHAPTER XXIV.

#### OF THE NATURAL ATTRIBUTES OF THE DEITY.

|                                                                                                                                                                                                    |     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| Attributes of the Deity revealed to us. How they concern us. Omnipotence and omniscience. The omnipresence of God. Definition of eternity: self-existence; necessary existence; spirituality . . . | 454 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

### CHAPTER XXV.

#### THE UNITY OF THE DEITY.

|                                                                                                                                                               |     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| Uniformity of plan in the universe. Condition of the Planets. Uniformity in action of the laws of nature. Analogies in development of animals. Also in plants | 462 |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

### CHAPTER XXVI.

#### THE GOODNESS OF THE DEITY.

|                                                   |  |

## INTRODUCTION.

THE Author, in the commencement of the twelfth chapter of this Treatise, refers to an idea or supposition vaguely entertained by certain writers of his time, that, in creation, some general plan might have proceeded from a “fixed necessity in the nature of things;” and then pertinently inquires how, if such be the case, could it “accommodate itself to the various wants and uses which it had to serve under different circumstances and on different occasions.”

This idea, however, had not in his time acquired sufficient support or currency among men of science to entitle it to any serious consideration in this justly celebrated work. It is accordingly merely mentioned to be put aside; and the argument maintained in these pages is based on the belief, that the living organisms in which intelligent design is traced were originally formed in a mature and finished state, and that each was endowed with a capacity of reproducing its like, by originating a new germ which

should be developed, through a natural process of growth, until it attained the same maturity of form and structure, without essential variation from the primitive type.

No doubt if Paley could have foreseen that the idea, casually mentioned by him and then dismissed, would at a later date have been revived in a far more attractive and consistent form, and under the name of the "Theory of Evolution" have enlisted on its side the support of so many able Naturalists and Biologists, he would have shown in what manner his argument might be adapted to this view of Nature. Therefore, in issuing a new and revised edition of his work, it may be permitted without presumption to preface it with a few remarks on this point.

The term "Evolution" is used by naturalists to signify the progressive development, under the operation of natural laws, of more complex and highly organized beings from those of simpler or lower type: or, to express the same idea in the words of one of the earliest and chief advocates of this theory (Dr. Darwin), "probably all the organic beings which have ever lived on this earth have descended from some one primordial form, into which life was first breathed."

---

In considering the effect of this view on Paley's line of argument, any reference to Man, as a moral and responsible agent, is designedly excluded.

It must be confessed that on our author's supposition of the original formation of the various organisms, in a matured and perfect state, the argument from the appearances of design is more obvious and direct, than it can be on the modern theory of evolution by natural agencies, or "a fixed necessity in the nature of things." If each matured living organism was originally framed to perform, with complete efficiency and perfect adaptation to surrounding circumstances, its many and intricate functions, the inference that Intelligence must have designed and formed it for its office is so obvious and cogent, as to command a ready assent from the common sense of mankind. But according to the theory of gradual development, the varied and beautiful examples of mechanism which we witness in the structure of animals, and their marvellous adaptation to the uses required of them, are held to be the natural consequence of evolutionary agencies, without immediate creative interference or the direct exercise of designing and constructing intelligence. Hence it may be affirmed by some, to whom this theory appears to be established

by sufficient proof, that it is fatal to the argument from the appearances of design. It was not an intelligent Designer, they may say, who skilfully perfected each form of life, in its relation to surrounding circumstances, and thereby adapted it to the special sphere of its existence; but it was by the agency of natural forces and of these surrounding conditions, exerted by imperceptible steps through an indefinite period, that a simple, primordial form has been progressively developed and fashioned, until we are presented with the complex and exquisite models of living mechanism, that excite our admiration, and impress our minds with the idea of contrivance and design.

Without attempting to question the sufficiency of the facts, or to discuss, either on scientific or other grounds, the validity of the arguments adduced in favour of this theory, the object of these introductory remarks is to point out, that the modern doctrine of evolution does not necessarily carry with it a confutation of the argument from the appearances of design. If this theory shall ever take its place among the universally recognized truths of Science, it will undoubtedly affect what may be called the incidence of the argument, and render the application of it more remote. But a little

consideration will show that the argument itself will retain its essential validity, and by no means be robbed of its force, or become antiquated or useless.

Lord Bacon, in his "Confession of Faith," remarks that "the laws of nature, which now remain and govern inviolably till the end of the world, began to be in force when God rested from His work. . . . Nevertheless, He doth accomplish and fulfil His divine will, in all things, great and small, general and particular, as fully and exactly by providence as He could do by miracle and new creation, though His working be not immediate or direct, but by compass; not violating nature, which is His own law, upon His creatures."

In like manner the sagacity of Bishop Butler enabled him to anticipate the precise question at issue in this conflict, when he wrote that, "an intelligent Author of Nature being supposed, it makes no difference in the matter before us, whether He acts in nature every moment, or at once contrived and executed His own part in the plan of the world." On this unquestionable ground it may be said, with equal force, that however far back the direct interference or action of the Designer is removed, that interference or action is not got

rid of, but only put back to an earlier stage, where the necessity for it exists as much as ever. If we suppose that the theory of evolution, in its most unqualified acceptation, is true, and that the existing condition of our globe, including its living tenants, has been fashioned from formless atoms or molecules of matter, under the guidance of natural forces and laws, still we should not be thereby enabled to dispense with an intelligent Designer, who in the beginning framed these laws, determined the agency of these forces, and endowed these atoms with the properties which have fitted them to evolve out of themselves the marvellous fabric, which is so varied in all its details and so perfect in all its relations.

Design does not cease to be design because the Designer's hand, instead of manufacturing the organisms out of the raw material, manufactured the material in such a way, and with such consummate skill, as to enable it in the course of ages to run itself, so to speak, into a myriad shapes of life and beauty. An analogous instance of evolution is witnessed in the reproduction and development of the highest forms of animal life, including man, from an ovum or simple germ of living matter. Here the law of like producing like is uniform, and

the limit of development is defined and constant; yet the mystery of the evolution of a whole creation is only the same in kind, as that of the development from the germ of each creature, especially if that creature be, like man, of a high type.

But, it has been asked, what proof have we that these elementary atoms were created— are not self-existent and eternal? The opinion of Sir John Herschel, embodied in his memorable words, that the elementary molecules possess “all the characteristics of manufactured articles,” and the same conviction expressed by other eminent physicists, has been recently disputed. In the absence of conclusive evidence on this subtle subject of inquiry, the unsatisfied reader has to make his election between the alternative probability of the antecedent existence of an Intelligent Creative Power, and the self-existence and marvellous self-endowment of the elementary molecules.

Thus, if it be conceded that matter was created, even were the theory of evolution established without reservation by irrefragable proof, it would still leave the inference of intelligent design untouched, and would only put back the stage at which the Designer’s hand exerted its fashioning energy. To have created

the material atoms in the beginning, and to have endowed them with inherent attributes and capabilities, sufficing, under favouring circumstances, to produce the varied combinations which constitute our organic and inorganic world, is virtually to have created everything which has since grown out of them ; and if, on the theory of direct creation, we were justified in our inference of an intelligent Creator, surely we cannot hesitate to adopt the same conclusion, if we accept the theory of evolution, the comprehensive simplicity of which, whether it be true or false, presents us with a grand conception of Creative Power.

In conclusion, the reader is reminded that this volume deals with no more than the first step in the progress towards Christian belief. In another work, the “Evidences of Christianity,” Paley has taken up the subject at the point where this volume leaves it, and has continued the argument by pointing out the antecedent probability that the God, Whom nature declares, should care for and reveal Himself to His creatures ; and then proceeding to show how cogent is the evidence to prove that He has actually revealed Himself to us in Jesus Christ.

## CHAPTER I.

### STATE OF THE ARGUMENT.

IN crossing a heath, suppose I pitched my foot against a *stone*, and were asked how the stone came to be there ; I might possibly answer, that, for anything I knew to the contrary, it had lain there for ever; nor would it perhaps be very easy to show the absurdity of this answer.<sup>1</sup> But suppose I had found a *watch* upon the ground, and it should be inquired how the watch happened to be in that place ; I should hardly think of the answer which I had before given, that, for anything I knew, the watch might have always

<sup>1</sup> The history of the stone may be read now by the light of Geology : it could not have lain there for ever. But this does not affect the argument.—[ED.]

been there. Yet why should not this answer serve for the watch as well as for the stone? why is it not as admissible in the second case as in the first? For this reason, and for no other, viz. that, when we come to inspect the watch, we perceive (what we could not discover in the stone) that its several parts are framed and put together for a purpose, e. g. that they are so formed and adjusted as to produce motion, and that motion so regulated as to point out the hour of the day; that, if the different parts had been differently shaped from what they are, of a different size from what they are, or placed after any other manner, or in any other order, than that in which they are placed, either no motion at all would have been carried on in the machine, or none which would have answered the use that is now served by it. To reckon up a few of the plainest of these parts, and of their offices, all tending to one result:—We see a cylindrical box containing a coiled elastic spring, which, by its endeavour to relax itself, turns round the box. We next observe a flexible chain (artificially wrought for the sake of flexure), communicating the action of the spring from the box to the fusee. We then find a series of wheels, the teeth of which catch in, and apply to, each other, conducting the motion from the

---

fusee to the balance, and from the balance to the pointer; and at the same time, by the size and shape of those wheels, so regulating that motion as to terminate in causing an index, by an equable and measured progression, to pass over a given space in a given time. We take notice that the wheels are made of brass in order to keep them from rust; the springs of steel, no other metal being so elastic; that over the face of the watch there is placed a glass, a material employed in no other part of the work, but in the room of which, if there had been any other than a transparent substance, the hour could not be seen without opening the case. This mechanism being observed (it requires indeed an examination of the instrument, and perhaps some previous knowledge of the subject, to perceive and understand it; but being once, as we have said, observed and understood), the inference, we think, is inevitable, that the watch must have had a maker: that there must have existed, at some time, and at some place or other, an artificer or artificers, who formed it for the purpose which we find it actually to answer; who comprehended its construction, and designed its use.

I. Nor would it, I apprehend, weaken the conclusion, that we had never seen a watch

made ; ~~that~~ we had never known an artist capable of making one ; that we were altogether incapable of executing such a piece of workmanship ourselves, or of understanding in what manner it was performed ; all this being no more than what is true of some exquisite remains of ancient art, of some lost arts, and, to the generality of mankind, of the more curious productions of modern manufacture. Does one man in a million know how oval frames are turned ? Ignorance of this kind exalts our opinion of the unseen and unknown artist's skill, if he be unseen and unknown, but raises no doubt in our minds of the existence and agency of such an artist, at some former time, and in some place or other. Nor can I perceive that it varies at all the inference, whether the question arise concerning a human agent, or concerning an agent of a different species, or an agent possessing, in some respects, a different nature.

II. Neither, secondly, would it invalidate our conclusion, ~~that~~ the watch sometimes went wrong, or ~~that~~ it seldom went exactly right. The purpose of the machinery, the design, and the designer, might be evident, and in the case supposed would be evident, in whatever way we accounted for the irregularity of the movement, or whether we could account for it or not. It

---

is not necessary that a machine be perfect, in order to show with what design it was made: still less necessary, where the only question is, whether it were made with any design at all.

III. Nor, thirdly, would it bring any uncertainty into the argument, if there were a few parts of the watch concerning which we could not discover, or had not yet discovered, in what manner they conduced to the general effect; or even some parts, concerning which we could not ascertain, whether they conduced to that effect in any manner whatever. For, as to the first branch of the case; if by the loss, or disorder, or decay of the parts in question, the movement of the watch were found in fact to be stopped, or disturbed, or retarded, no doubt would remain in our minds as to the utility or intention of these parts, although we should be unable to investigate the manner according to which, or the connexion by which, the ultimate effect depended upon their action or assistance; and the more complex is the machine, the more likely is this obscurity to arise. Then, as to the second thing supposed; namely, that there were parts which might be spared, without prejudice to the movement of the watch, and that we had proved this by experiment,—these superfluous parts, even if we were completely

assured that they were such, would not vacate the reasoning which we had instituted concerning other parts. The indication of contrivance remained, with respect to them, nearly as it was before.

IV. Nor, fourthly, would any man in his senses think the existence of the watch, with its various machinery, accounted for, by being told that it was one out of possible combinations of material forms; that whatever he had found in the place where he found the watch, must have contained some internal configuration or other; and that this configuration might be the structure now exhibited, viz. of the works of a watch, as well as a different structure.

V. Nor, fifthly, would it yield his inquiry more satisfaction to be answered, <that there existed in things a principle of order, which had disposed the parts of the watch into their present form and situation. He never knew a watch made by the principle of order; nor can he even form to himself an idea of what is meant by a principle of order, distinct from the intelligence of the watchmaker.

VI. Sixthly, he would be surprised to hear that the mechanism of the watch was no proof of contrivance, only a motive to induce the mind to think so.

VII. And not less surprised to be informed, that the watch in his hand was nothing more than the result of the laws of *metallic* nature. It is a perversion of language to assign any law as the efficient, operative cause of anything. A law presupposes an agent; this is only the mode, according to which an agent proceeds; it implies a power; for it is the order according to which that power acts. Without this agent, without this power, which are both distinct from itself, the *law* does nothing, is nothing. The expression, "the law of metallic nature," may sound strange and harsh to a philosophic ear; but it seems quite as justifiable as some others which are more familiar to him, such as "the law of vegetable nature," "the law of animal nature," or indeed as "the law of nature" in general, when assigned as the cause of phenomena, in exclusion of agency and power; or when it is substituted into the place of these.

VIII. Neither, lastly, would our observer be driven out of his conclusion, or from his confidence in its truth, by being told that he knew nothing at all about the matter. He knows enough for his argument: he knows the utility of the end; he knows the subserviency and adaptation of the means to the end. These

points being known, his ignorance of other points, his doubts concerning other points, affect not the certainty of his reasoning. The consciousness of knowing little need not beget a ] distrust of that which he does know.

## CHAPTER II.

### STATE OF THE ARGUMENT, CONTINUED.

SUPPOSE, in the next place, that the person who found the watch should, after some time, discover that, in addition to all the properties which he had hitherto observed in it, it possessed the unexpected property of producing, in the course of its movement, another watch like itself (the thing is conceivable); that it contained within it a mechanism, a system of parts, a mould for instance, or a complex adjustment of lathes, files, and other tools, evidently and separately calculated for this purpose; let us inquire, what effect ought such a discovery to have upon his former conclusion.

I. The first effect would be to increase his admiration of the contrivance, and his conviction of the consummate skill of the contriver. Whether he regarded the object of the contrivance, the distinct apparatus, the intricate,

yet in many parts intelligible mechanism, by which it was carried on, he would perceive, in this new observation, nothing but an additional reason for doing what he had already done—for referring the construction of the watch to design, and to supreme art. If that construction *without* this property, or which is the same thing, before this property had been noticed, proved intention and art to have been employed about it; still more strong would the proof appear, when he came to the knowledge of this further property, the crown and perfection of all the rest.

II. He would reflect, that though the watch before him were, *in some sense*, the maker of the watch, which was fabricated in the course of its movements, yet it was in a very different sense from that in which a carpenter, for instance, is the maker of a chair; the author of its contrivance, the cause of the relation of its parts to their use. With respect to these, the first watch was no cause at all to the second: in no such sense as this was it the author of the constitution and order, either of the parts which the new watch contained, or of the parts by the aid and instrumentality of which it was produced. We might possibly say, but with great latitude of expression, that a stream of water

ground corn; but no latitude of expression would allow us to say, no stretch of conjecture could lead us to think, that the stream of water built the mill, though it were too ancient for us to know who the builder was. What the stream of water does in the affair, is neither more nor less than this; by the application of an unintelligent impulse to a mechanism previously arranged, arranged independently of it, and arranged by intelligence, an effect is produced, viz. the corn is ground. But the effect results from the arrangement. The force of the stream cannot be said to be the cause or author of the effect, still less of the arrangement. Understanding and plan in the formation of the mill were not the less necessary, for any share which the water has in grinding the corn: yet is this share the same as that which the watch would have contributed to the production of the new watch, upon the supposition assumed in the last section. Therefore,

III. Though it be now no longer probable, that the individual watch, which our observer had found, was made immediately by the hand of an artificer, yet doth not this alteration in anywise affect the inference that an artificer had been originally employed and concerned in the production. The argument from design

remains as it was. Marks of design and contrivance are no more accounted for now than they were before. In the same thing we may ask for the cause of different properties. We may ask for the cause of the colour of a body, of its hardness, of its heat; and these causes may be all different. We are now asking for the cause of that subserviency to a use, that relation to an end, which we have remarked in the watch before us. No answer is given to this question, by telling us that a preceding watch produced it. There cannot be design without a designer; contrivance without a contriver; order without choice; arrangement, without anything capable of arranging; subserviency and relation to a purpose, without that which could intend a purpose; means suitable to an end, and executing their office in accomplishing that end, without the end ever having been contemplated, or the means accommodated to it. Arrangement, disposition of parts, subserviency of means to an end, relation of instruments to a use, imply the presence of intelligence and mind. No one, therefore, can rationally believe that the insensible, inanimate watch, from which the watch before us issued, was the proper cause of the mechanism we so much admire in it—could be truly said to have

constructed the instrument, disposed its parts, assigned their office, determined their order, action, and mutual dependency, combined their several motions into one result, and that also a result connected with the utilities of other beings. All these properties, therefore, are as much unaccounted for as they were before.

IV. Nor is anything gained by running the difficulty farther back, i. e., by supposing the watch before us to have been produced from another watch, that from a former, and so on indefinitely. Our going back ever so far brings us no nearer to the least degree of satisfaction upon the subject. Contrivance is still unaccounted for. We still want a contriver. A designing mind is neither supplied by this supposition, nor dispensed with. If the difficulty were diminished the further we went back, by going back indefinitely we might exhaust it. And this is the only case to which this sort of reasoning applies. Where there is a tendency, or, as we increase the number of terms, a continual approach towards a limit, *there*, by supposing the number of terms to be what is called infinite, we may conceive the limit to be attained; but where there is no such tendency, or approach, nothing is effected by lengthening the series. There is no difference as to the

point in question (whatever there may be as to many points), between one series and another; between a series which is finite, and a series which is infinite. A chain, composed of an infinite number of links, can no more support itself, than a chain composed of a finite number of links. And of this we are assured (though we never *can* have tried the experiment), because, by increasing the number of links, from ten for instance to a hundred, from a hundred to a thousand, &c. we make not the smallest approach, we observe not the smallest tendency, towards self-support. There is no difference in this respect (yet there may be a great difference in several respects) between a chain of a greater or less length, between one chain and another, between one that is finite and one that is infinite. This very much resembles the case before us. The machine which we are inspecting demonstrates, by its construction, contrivance and design. Contrivance must have had a contriver; design, a designer; whether the machine immediately proceeded from another machine or not. That circumstance alters not the case. That other machine may, in like manner, have proceeded from a former machine: nor does that alter the case; contrivance must have had a contriver. That former one from one preceding

---

it : no alteration still ; a contriver is still necessary. No tendency is perceived, no approach towards a diminution of this necessity. It is the same with any and every succession of these machines ; a succession of ten, of a hundred, of a thousand ; with one series, as with another ; a series which is finite, as with a series which is infinite. In whatever other respects they may differ, in this they do not. In all equally, contrivance and design are unaccounted for.

The question is not simply, How came the first watch into existence ? which question, it may be pretended, is done away by supposing the series of watches thus produced from one another to have been infinite, and consequently to have had no such *first*, for which it was necessary to provide a cause. This, perhaps, would have been nearly the state of the question, if nothing had been before us but an unorganized, unmechanized substance, without mark or indication of contrivance. It might be difficult to show that such substance could not have existed from eternity, either in succession (if it were possible, which I think it is not, for unorganized bodies to spring from one another), or by individual perpetuity. But that is not the question now. To suppose it to be so, is to suppose that it made no difference

whether we had found a watch or a stone. As it is, the metaphysics of that question have no place; for, in the watch which we are examining, are seen contrivance, design; an end, a purpose; means for the end, adaptation to the purpose. And the question which irresistibly presses upon our thoughts is, whence this contrivance and design? The thing required is the intending mind, the adapting hand, the intelligence by which that hand was directed. This question, this demand, is not shaken off, by increasing a number or succession of substances, destitute of these properties; nor the more, by increasing that number to infinity. If it be said, that, upon the supposition of one watch being produced from another in the course of that other's movements, and by means of the mechanism within it, we have a cause for the watch in my hand, viz. the watch from which it proceeded. I deny, that for the design, the contrivance, the suitableness of means to an end, the adaptation of instruments to a use (all which we discover in the watch), we have any cause whatever. It is in vain, therefore, to assign a series of such causes, or to allege that a series may be carried back to infinity; for I do not admit that we have yet any cause at all of the phenomena, still less any series of causes either

finite or infinite. Here is contrivance, but no contriver; proofs of design, but no designer.

V. Our observer would further also reflect, that the maker of the watch before him was, in truth and reality, the maker of every watch produced from it; there being no difference (except that the latter manifests a more exquisite skill) between the making of another watch with his own hands, by the mediation of files, lathes, chisels, &c. and the disposing, fixing, and inserting of these instruments, or of others equivalent to them, in the body of the watch already made, in such a manner as to form a new watch in the course of the movements which he had given to the old one. It is only working by one set of tools instead of another.

The conclusion which the *first* examination of the watch, of its works, construction and movement, suggested, was, that it must have had, for the cause and author of that construction, an artificer who understood its mechanism and designed its use. This conclusion is invincible. A *second* examination presents us with a new discovery. The watch is found, in the course of its movement, to produce another watch, similar to itself; and not only so, but we perceive in it a system of organization, separately calculated for that purpose.

What effect would this discovery have, or ought it to have, upon our former inference? What, as hath already been said, but to increase, beyond measure, our admiration of the skill, which had been employed in the formation of such a machine? Or shall it, instead of this, all at once turn us round to an opposite conclusion, viz. that no art or skill whatever has been concerned in the business, although all other evidences of art and skill remain as they were, and this last and supreme piece of art be now added to the rest? Can this be maintained without absurdity? Yet this is atheism.

## CHAPTER III.

## APPLICATION OF THE ARGUMENT.

THIS is atheism: for every indication of contrivance, every manifestation of design, which existed in the watch, exists in the works of nature; with the difference, on the side of nature, of being greater and more, and that in a degree which exceeds all computation. I mean that the contrivances of nature surpass the contrivances of art, in the complexity, subtlety, and curiosity of the mechanism; and still more, if possible, do they go beyond them in number and variety; yet, in a multitude of cases, are not less evidently mechanical, not less evidently contrivances, not less evidently accommodated to their end, or suited to their office, than are the most perfect productions of human ingenuity.

I know no better method of introducing so large a subject, than that of comparing a single

thing with a single thing ; an eye, for example, with a telescope. As far as the examination of the instrument goes, there is precisely the same proof that the eye was made for vision, as there is that the telescope was made for assisting it. They are made upon the same principles ; both being adjusted to the laws by which the transmission and refraction of rays of light are regulated. I speak not of the origin of the laws themselves ; but such laws being fixed, the construction, in both cases, is adapted to them. For instance ; these laws require, in order to produce the same effect, that the rays of light, in passing from water into the eye, should be refracted by a more convex surface than when it passes out of air into the eye. Accordingly we find that the eye of a fish, in that part of it called the crystalline lens, is much rounder than the eye of terrestrial animals. What plainer manifestation of design can there be than this difference? What could a mathematical-instrument-maker have done more, to show his knowledge of this principle, his application of that knowledge, his suiting of his means to his end; I will not say to display the compass or excellence of his skill and art, for in these all comparison is indecorous, but to testify counsel choice consideration purpose?

To some it may appear a difference sufficient to destroy all similitude between the eye and

SECTION OF THE EYE.

*a*, the cornea; *b*, the aqueous humour; *c c*, the iris; *d*, the crystalline lens; *e*, the vitreous humour filling the ball of the eye; *ffff*, the retina; *gg*, the optic nerve; *h h*, two of the straight muscles for raising and depressing the eye.

the telescope, that the one is a perceiving organ, the other an unperceiving instrument. The fact is that they are both instruments. And, as to the mechanism, at least as to mechanism being employed, and even as to the kind of it, this circumstance varies not the analogy at all. For, observe what the constitution of the

eye is. It is necessary, in order to produce distinct vision, that an image or picture of the object be formed at the bottom of the eye, i.e. on the *Retina*, or expansion of the nerve of

SECTION OF THE EYE, OF THE NATURAL SIZE,  
showing the same parts in a shaded manner.

vision, which communicates the impression to the brain. Whence this necessity arises, or how the picture is connected with the sensation, or contributes to it, it may be difficult, nay we will confess, if you please, impossible for us to

search out. But the present question is not concerned in the inquiry. It may be true that, in this and in other instances, we trace mechanical contrivance a certain way; and that then we come to something which is not mechanical, or which is inscrutable. But this affects not the certainty of our investigation, as far as we have gone. The difference between an animal and an automatic statue consists in this,—that, in the animal, we trace the mechanism to a certain point, and then we are stopped; either the mechanism becoming too subtle for our discernment, or something else beside the known laws of mechanism taking place: whereas, in the automaton, for the comparatively few motions of which it is capable, we trace the mechanism throughout. But, up to the limit, the reasoning is as clear and certain in the one case as in the other. In the example before us, it is a matter of certainty, because it is a matter which experience and observation demonstrate, that the formation of an image at the bottom of the eye is necessary to perfect vision. The image itself can be shown. Whatever affects the distinctness of the image affects the distinctness of vision. The formation then of such an image being necessary (no matter how) to the sense of sight, and to the exercise

of that sense, the apparatus by which it is formed is constructed and put together, not only with infinitely more art, but upon the self-same principles of art, as in the telescope or the camera obscura. The perception arising from the image may be laid out of the question; for the production of the image, these are instruments of the same kind. The end is the same, the means are the same. The purpose in both is alike; the contrivance for accomplishing that purpose is in both alike. The lenses of the telescope, and the humours of the eye, bear a resemblance to one another, in their figure, their position, and in their power over the rays of light, viz. in bringing each pencil to a point at the right distance from the lens; namely, in the eye, at the exact place where the membrane is spread to receive it. How is it possible, under circumstances of such close affinity, and under the operation of equal evidence, to exclude contrivance from the one; yet to acknowledge the proof of contrivance having been employed, as the plainest and clearest of all propositions, in the other?

The resemblance between the two cases is still more accurate, and obtains in more points than we have yet represented, or than we are, on the first view of the subject, aware of. In

---

dioptric telescopes there is an imperfection of this nature. Pencils of light, in passing through glass lenses, are separated into different colours, thereby tinging the object, especially the edges of it, as if it were viewed through a prism. To correct this inconvenience had been long a desideratum in the art. At last it came into the mind of a sagacious optician to inquire how this matter was managed in the eye; in which there was exactly the same difficulty to contend with as in the telescope. His observation taught him that in the eye the evil was cured by combining lenses composed of different substances, i. e., of substances which possessed different refracting powers. Our artist borrowed thence his hint, and produced a correction of the defect by imitating, in glasses made from different materials, the effects of the different humours through which the rays of light pass before they reach the bottom of the eye. Could this be in the eye without purpose, which suggested to the optician the only effectual means of attaining that purpose?

But further, there are other points not so much, perhaps, of strict resemblance between the two, as of superiority of the eye over the telescope, yet of a superiority which, being

founded in the laws that regulate both, may furnish topics of fair and just comparison. Two things were wanted to the eye which were not wanted (at least in the same degree) to the telescope ; and these were the adaptation of the organ ; first, to different degrees of light ; and secondly, to the vast diversity of distance at which objects are viewed by the naked eye, viz., from a few inches to as many miles. These difficulties present not themselves to the maker of the telescope. He wants all the ~~light~~ he can get, and he never directs his instrument to objects near at hand. In the eye, both these cases were to be provided for ; and for the purpose of providing for them a subtle and appropriate mechanism is introduced.

I. In order to exclude excess of light, when it is excessive, and to render objects visible under obscurer degrees of it, when no more can be had, the hole or aperture in the eye, through which the light enters, is so formed as to contract or dilate itself for the purpose of admitting a greater or less number of rays at the same time. The chamber of the eye is a camera obscura, which, when the light is too small, can enlarge its opening ; when too strong, can again contract it ; and that without any other assistance than that of its own

exquisite machinery. It is self-adjusting in the following way :—The impression, which a varying degree of intensity of light makes on the retina, is conveyed to the brain by the nerve of vision ; and thence, as a consequence of this stimulus, a reflex current of nerve force is

THE IRIS,  
showing the arrangement of the circular and radiating fibres.

emitted, and conveyed by appropriate nerve-fibres to the muscular ring or iris, which, by its action, can either contract or expand the pupil. It is further, also, in the human subject to be observed, that this hole in the eye, which we call the pupil, under all its different dimensions, retains its exact circular shape. This is a structure extremely artificial. Let an artist

only try to execute the same ; he will find that his threads and strings must be disposed with great consideration and contrivance to make a circle which shall continually change its diameter, yet preserve its form. This is done in the eye by an application of fibres, i. e., of contractile strings, similar in their position and action to what an artist would endeavour to procure, and must employ if he had the same piece of workmanship to perform.

II. The second difficulty which has been stated was the suiting of the same organ to the perception of objects that lie near at hand, within a few inches, we will suppose, of the eye, and of objects which are placed at a considerable distance from it, that, for example, of as many furlongs (I speak in both cases of the distance at which distinct vision can be exercised). Now this, according to the principles of optics, that is, according to the laws by which the transmission of light is regulated (and these laws are fixed), could not be done without the organ itself undergoing an alteration, and receiving an adjustment, that might correspond with the exigency of the case, that is to say, with the different inclination to one another under which the rays of light reached it. Rays issuing from points placed at a small

---

distance from the eye, and which consequently must enter the eye in a spreading or diverging order, cannot, by the same optical instrument in the same state, be brought to a point, i. e. be made to form an image in the same place, with rays proceeding from objects situated at a much greater distance, and which rays arrive at the eye in directions nearly (and physically speaking) parallel. It requires a rounder lens to do it. The point of concourse behind the lens must fall critically upon the retina, or the vision is confused ; yet, other things remaining the same, this point, by the immutable properties of light, is carried further back when the rays proceed from a near object, than when they are sent from one that is remote. A person who was using an optical instrument would manage this matter by changing, as the occasion required, his lens or his telescope, or by adjusting the distance of his glasses with his hand or his screw ; but how is it to be managed in the eye ? What the alteration was, or in what part of the eye it took place, or by what means it was effected (for if the known laws which govern the refraction of light be maintained, some alteration in the state of the organ there must be), had long formed a subject of inquiry and conjecture.

The change, though sufficient for the purpose, is so minute as to elude ordinary observation. The adjustment to distance is most likely dependent on the varying convexity of the lens, which is determined by the pressure to which it is subjected, through the indirect agency of a special muscular contrivance. These changes in the eye vary its power over the rays of light in such a manner and degree as to produce exactly the effect which is wanted, viz. the formation of an image *upon the retina*, whether the rays come to the eye in a state of divergency, which is the case when the object is near to the eye, or come parallel to one another, which is the case when the object is placed at a distance. Can anything be more decisive of contrivance than this is? The most secret laws of optics must have been known to the author of a structure endowed with such a capacity of change. It is as though an optician, when he had a nearer object to view, should *rectify* his instrument by putting in another glass, at the same time drawing out also his tube to a different length.

Observe a new-born child first lifting up its eyelids. What does the opening of the curtain discover? The anterior part of two pellucid globes, which, when they come to be examined,

---

are found to be constructed upon strictly optical principles ; the self-same principles upon which we ourselves construct optical instruments. We find them perfect for the purpose of forming an image by refraction, composed of parts executing different offices ; one part having fulfilled its office upon the pencil of light, delivering it over to the action of another part; that to a third, and so onward : the progressive action depending for its success upon the nicest and minutest adjustment of the parts concerned ; yet, these parts so in fact adjusted as to produce, not by a simple action or effect, but by a combination of actions and effects, the result which is ultimately wanted. And forasmuch as this organ would have to operate under different circumstances, with strong degrees of light, and with weak degrees, upon near objects, and upon remote ones, these differences demanded, according to the laws by which the transmission of light is regulated, a corresponding diversity of structure ; that the aperture, for example, through which the light passes, should be larger or less ; the lenses rounder or flatter, or that their distance from the tablet, upon which the picture is delineated, should be shortened or lengthened : this, I say, being the case, and the difficulty to which the eye was to be

adapted, we find its several parts capable of being occasionally changed, and a most artificial apparatus provided to produce that change. This is far beyond the common regulator of a watch, which requires the touch of a foreign hand to set it; but it is not altogether unlike Harrison's contrivance for making a watch regulate itself, by inserting within it a machinery, which, by the artful use of the different expansion of metals, preserves the equability of the motion under all the various temperatures of heat and cold in which the instrument may happen to be placed. The ingenuity of this last contrivance has been justly praised. Shall, therefore, a structure which differs from it, chiefly by surpassing it, be accounted no contrivance at all? or, if it be a contrivance, that it is without a contriver!

But this, though much, is not the whole; by different species of animals the faculty we are describing is possessed, in degrees suited to the different range of vision which their mode of life, and of procuring their food, requires. *Birds*, for instance, in general, procure their food by means of their beak; and, the distance between the eye and the point of the beak being small, it becomes necessary that they should have the power of seeing very near

objects distinctly. On the other hand, from being often elevated much above the ground, living in air, and moving through it with great velocity, they require, for their safety, as well as for assisting them in descrying their prey, a power of seeing at a great distance; a power of which, in birds of rapine, surprising examples are given. The fact accordingly is, that two peculiarities are found in the eyes of birds, both tending to *facilitate* the change upon which the adjustment of the eye to different distances depends. The one is a bony, yet, in most species, a flexible rim or hoop, surrounding the broadest part of the eye; which, confining the action of the muscles to that part, increases the effect of their lateral pressure upon the orb, by which pressure its axis is elongated for the purpose of looking at very near objects. The other is a vascular membrane, called the marsupium, adapted to alter the position of the crystalline lens, and to fit the same eye for the viewing of near or distant objects. By these means the eyes of birds can pass from one extreme to another of their scale of adjustment, with more ease and readiness than the eyes of other animals.

This property of adjustment in birds requires additional space; therefore the antero-posterior

axis of the eye is very much elongated, and the aqueous fluid in front of the lens is much more abundant: thus, the pressure exerted operates both by pressing the cornea forwards, and thereby rendering it more conical, and also by pressing the lens backwards. The marsupium, or pecten, is an erectile, vascular organ, varying in its dimensions according to the quantity of blood it contains. Its position in the interior of the vitreous humour imparts to it the property, when distended, of forcing the lens forwards: it is covered with pigment.

The eyes of *fishes* also, compared with those of terrestrial animals, exhibit certain distinctions of structure, adapted to their state and element. We have already observed upon the figure of the crystalline lens compensating by its roundness the density of the medium through which the light passes. To which we have to add, that the eyes of fish, in their natural and indolent state, appear to be adjusted to near objects, in this respect differing from the human eye, as well as those of quadrupeds and birds. The ordinary shape of the fish's eye being in a much higher degree convex than that of land-animals, a corresponding difference attends its muscular conformation, viz. that it is throughout calculated for flattening the eye.

The *iris* also in the eyes of fish does not admit of contraction. This is a great difference, of which the probable reason is, that the diminished light in water is never too strong for the retina. The spherical form of the dense crystalline lens necessitates its approximation to the back of the eye, in order that the rays of light may be brought to a focus on the retina. The aqueous humour being useless, and the vitreous humour almost so, in deflecting the rays of light after passing through water, are both limited in quantity; consequently the antero-posterior diameter of the eye-ball is flattened. Further its supporting membrane, the sclerotic, is strengthened by the presence of cartilaginous plates, and in some of the large fishes converted into bone, in order to resist the effect of lateral pressure, and consequent alteration in the form of the globe. The pupil is large and generally motionless, and true eyelids are absent.

In the *eel*, which has to work its head through sand and gravel, the roughest and hardest substances, there is placed before the eye, and at some distance from it, a transparent, horny, convex case or covering, which, without obstructing the sight, defends the organ. To such an animal, could anything be more wanted, or more useful?

Thus, in comparing the eyes of different kinds of animals, we see, in their resemblances and distinctions, one general plan laid down, and that plan varied with the varying exigencies to which it is to be applied.

There is one property, however, commonly met with; namely, that the optic nerve enters the bottom of the eye, not in the centre or middle, but a little on one side; not in the point where the axis of the eye meets the retina, but between that point and the nose. The difference which this makes is, that no part of an object is unperceived by both eyes at the same time. The spot at which the optic nerve spreads itself to form the retina is the only point in this membrane which is insensible to light. This is about one tenth of an inch to the inner side of the axis of the eye, and therefore it does not interfere with vision.

In considering vision as achieved by the means of an image formed at the bottom of the eye, we can never reflect without wonder upon the smallness, yet correctness, of the picture, the subtlety of the touch, the fineness of the lines. A landscape of five or six square leagues is brought into a space of half an inch diameter; yet the multitude of objects which it contains are all preserved; are all discriminated in their

---

magnitudes, positions, figures, colours. The prospect from Hampstead-hill is compressed into the compass of a sixpence, yet circumstantially represented. A stage coach, travelling at its ordinary speed for half an hour, passes, in the eye, only over one twelfth of an inch, yet is this change of place in the image distinctly perceived throughout its whole progress; for it is only by means of that perception that the motion of the coach itself is made sensible to the eye. If anything can abate our admiration of the smallness of the visual tablet compared with the extent of vision, it is a reflection, which the view of nature leads us every hour to make, viz. that, in the hands of the Creator, great and little are nothing.

Sturmius held, that the examination of the eye was a cure for atheism. Beside that conformity to optical principles which its internal constitution displays, and which alone amounts to a manifestation of intelligence having been exerted in the structure; besides this, which forms, no doubt, the leading character of the organ, there is to be seen, in everything belonging to it and about it, an extraordinary degree of care, an anxiety for its preservation, due, if we may so speak, to its value and its tenderness. It is lodged in a strong,

deep, bony socket, composed by the junction of seven different bones, hollowed out at their edges. In some few species, as that of the coati-mondi, the orbit is not bony throughout; but whenever this is the case, the upper, which is the deficient part, is supplied by a cartilaginous ligament; a substitution which shows the same care. Within this socket it is embedded in fat, of all animal substances the best adapted both to its repose and motion. It is sheltered by the eyebrows; an arch of hair, which, like a thatched penthouse, prevents the sweat and moisture of the forehead from running down into it.

But it is still better protected by its *lid*. Of the superficial parts of the animal frame, I know none which, in its office and structure, is more deserving of attention than the eyelid. It defends the eye; it wipes it; it closes it in sleep; and its delicate texture is never encumbered with fat. Are there in any work of art whatever, purposes more evident than those which this organ fulfils? or an apparatus for executing those purposes more intelligible, more appropriate, or more mechanical? If it be overlooked by the observer of nature, it can only be because it is obvious and familiar. This is a tendency to be guarded against. We pass

by the plainest instances, whilst we are exploring those which are rare and curious ; by which conduct of the understanding, we sometimes neglect the strongest observations, being taken up with others, which, though more recondite and scientific, are, as solid arguments, entitled to much less consideration.

In order to keep the eye moist and clean (which qualities are necessary to its brightness and its use), a wash is constantly supplied by a secretion for the purpose; and the superfluous brine is conveyed to the nose through a perforation in the bone as large as a goose-quill ; or, more properly speaking, along two capillary tubes, one from either eyelid, which enter a duct, lodged in a canal passing through the bone. When once the fluid has entered the nose, it spreads itself upon the inside of the nostril, and is evaporated by the current of warm air, which, in the course of respiration, is continually passing over it. Can any pipe, or outlet, for carrying off the waste liquor from a dye-house or a distillery, be more mechanical than this is ? It is easily perceived that the eye must want moisture : but could the want of the eye generate the gland which produces the tear, or bore the hole by which it is discharged,—a hole through a bone ?

It is observable, that this provision is not found in fish,—the element in which they live supplying a constant lotion to the eye.

It were, however, injustice to dismiss the eye as a piece of mechanism, without noticing that most exquisite of all contrivances, the *nictitating membrane*, which is found in the eyes of birds and in a rudimentary form in those of many quadrupeds. Its use is to sweep the eye, which it does in an instant, to spread over it the lachrymal humour; to defend it also from sudden injuries; yet not totally, when drawn upon the pupil, to shut out the light. The commodiousness with which it lies folded up in the upper corner of the eye, ready for use and action, and the quickness with which it executes its purpose, are properties known and obvious to every observer; but what is equally admirable, though not quite so obvious, is the combination of two kinds of substance, muscular and elastic, and of two different kinds of action, by which the motion of this membrane is performed. It is not, as in ordinary cases, by the action of two antagonist muscles, one pulling forward and the other backward, that a reciprocal change is effected; but it is thus: the membrane itself is an elastic substance, capable of being drawn

out by force like a piece of elastic gum, and by its own elasticity returning, when the force is removed, to its former position. Such being its nature, in order to fit it up for its office, it is connected by a tendon or thread with a muscle in the back part of the eye: this tendon or thread, though strong, is so fine as not to obstruct the sight, even when it passes across it; and the muscle itself, being placed in the *back* part of the eye, derives from its situation the advantage, not only of being secure, but of being out of the way; which it would hardly have been in any position that could be assigned to it in the anterior part of the orb, where its function lies. When the muscle behind the eye contracts, the membrane, by means of the communicating thread, is instantly drawn over the fore part of it. When the muscular contraction (which is a positive, and, most probably, a voluntary effort) ceases to be exerted, the elasticity alone of the membrane brings it back again to its position. Does not this, if anything can do it, bespeak an artist, master of his work, acquainted with his materials? “Of a thousand other things,” say the French academicians, “we perceive not the contrivance, because we understand them only by the effects, of which we know not the

causes ; but we here treat of a machine, all the parts whereof are visible, and which need only be looked upon to discover the reasons of its motion and action.”<sup>1</sup>

In the configuration of the muscle which, though placed behind the eye, draws the nictitating membrane over the eye, there is what the authors, just now quoted, deservedly call a marvellous mechanism. In the cassowary this muscle is *passed through a loop formed by another muscle*; and is there inflected, as if it were round a pulley. This is a peculiarity; and observe the advantage of it. A single muscle with a straight tendon, which is the common muscular form, would have been sufficient, if it had had power to draw far enough. But the contraction necessary to draw the membrane over the whole eye, required a longer muscle than could lie straight at the bottom of the eye. Therefore, in order to have a greater length in a less compass, the cord of the main muscle makes an angle. This, so far, answers the end; but, still further, it makes an angle, not round a fixed pivot, but round a loop formed by another muscle; which

<sup>1</sup> Memoirs for a Natural History of Animals, by the Royal Academy of Sciences at Paris, done into English by order of the Royal Society, 1701, page 249.

---

second muscle, whenever it contracts, of course twitches the first muscle at the point of inflection, and thereby assists the action designed by both. This membrane exists in a rudimentary form in some quadrupeds, but is not moved by a special muscle, though it is lubricated by the secretion of a special gland.

Many other obvious illustrations of adaptation of structure to function in the eye might be added to the foregoing. The choroid coat with its black pigment, spread out immediately behind the retina, to absorb the transmitted rays of light, and thus obviate the confusion which would be otherwise produced, is a striking instance. The spontaneous movement of the eyes inwards or outwards is another; for it must be remembered that the muscle which draws one eye towards the nose must act in concert with that which directs the other eye away from it; yet the muscle which abducts each eye receives its nervous supply from corresponding nerves, though they do not act in concert. But the adaptation of all this exquisite mechanism in accordance with the laws of optics would be valueless, were not a certain part of the brain set apart and endowed with the special function of appreciating what we term light. This

specially-endowed portion of the sensorium is the true seat of the sense of sight ; the eye is but the optical instrument designed to produce a picture on the concave mirror at the back of the eye. 'The imperfection of either the nerve centre of vision, or of the modifying apparatus in front of it is fatal to sight ; both must be perfect in their mutual relations, and in their adaptation to the function to which they are jointly subservient.

One question may possibly have dwelt in the reader's mind during the perusal of these observations; namely, why should not the Deity have given to the animal the faculty of vision *at once*? Why this circuitous perception ; the ministry of so many means ; an element provided for the purpose; reflected from opaque substances, refracted through transparent ones ; and both according to precise laws ; then, a complex organ, an intricate and artificial apparatus, in order, by the operation of this element, and in conformity with the restrictions of these laws, to produce an image upon a membrane communicating with the brain ? Wherefore all this ? Why make the difficulty in order to surmount it ? If to perceive objects by some other mode than that of touch,

or objects which lay out of the reach of that sense, were the thing proposed; could not a simple volition of the Creator have communicated the capacity? Why resort to contrivance where power is omnipotent? Contrivance, by its very definition and nature, is the refuge of imperfection. To have recourse to expedients implies difficulty, impediment, restraint, defect of power. This question belongs to the other senses, as well as to sight; to the general functions of animal life, as nutrition, secretion, respiration, to the economy of vegetables; and indeed to almost all the operations of nature. The question, therefore, is of very wide extent · and amongst other answers which may be given to it, beside reasons of which probably we are ignorant, one answer is this: it is only by the display of contrivance, that the existence, the agency, the wisdom of the Deity, could be testified to His rational creatures. This is the scale by which we ascend to all the knowledge of our Creator which we possess, so far as it depends upon the phenomena, or the works of nature. Take away this, and you take away from us every subject of observation, and ground of reasoning! I mean as our rational faculties are formed at present. Whatever is done, God could have

done without the intervention of instruments or means ; but having framed laws for the government of matter, it is essential that mechanism should be employed to regulate the conduct of matter in accordance with these laws ; and it is in the construction of instruments, in the choice and adaptation of means, that a creative intelligence is seen. It is this which constitutes the order and beauty of the universe. God, therefore, has been pleased to prescribe limits to His own power, and to work His ends within those limits. The general laws of matter have perhaps the nature of these limits ; its inertia, its reaction ; the laws which govern the communication of motion, the refraction and reflection of light, the constitution of fluids non-elastic and elastic, the transmission of sound through the latter ; the laws of magnetism, of electricity ; and probably others, yet undiscovered. These are general laws ; and when a particular purpose is to be effected, it is not by making a new law, nor by the suspension of the old ones, nor by making them wind, and bend, and yield to the occasion (for nature with great steadiness adheres to and supports them) ; but it is, as we have seen in the eye, by the interposition of an apparatus, corresponding with these laws, and suited to

the exigency which results from them, that the purpose is at length attained. As we have said, therefore, God prescribes limits to His power, that He may let in the exercise, and thereby exhibit demonstrations of His wisdom. For then, i. e., such laws and limitations being laid down, it is as though one Being should have fixed certain rules; and, if we may so speak, provided certain materials; and, afterwards, have committed to another Being, out of these materials, and in subordination to these rules, the task of drawing forth a creation: a supposition which evidently leaves room, and induces indeed a necessity for contrivance. Nay, there may be many such agents, and many ranks of these. We do not advance this as a doctrine either of philosophy or of religion; but we say that the subject may safely be represented under this view, because the Deity, acting Himself by general laws, will have the same consequences upon our reasoning, as if He had prescribed these laws to another. It has been said that the problem of creation was, "attraction and matter being given, to make a world out of them;" and, as above explained, this statement perhaps does not convey a false idea.

We have made choice of the eye as an instance upon which to rest the argument of this chapter. Some single example was to be proposed; and the eye offered itself under the

THE EXTERNAL EAR,

exhibiting, in a well-formed male example, the channels and cavities for reflecting the sound into the auditory passage.

advantage of admitting of a strict comparison with optical instruments. The ear, it is probable, is no less artificially and mechanically adapted to its office than the eye. But we

know less about it: we do not so well understand the action, the use, or the mutual dependency of its internal parts. Its general form, however, both external and internal, is

GENERAL PLAN OF THE EAR.

*a*, the meatus auditorius externus, or external tube of the ear; *b*, the membrane of the drum of the ear; *c*, the chain of small bones lying within the drum; *f*, the semicircular canals; *e*, the cochlea; *d*, the eustachian tube.

sufficient to show that it is an instrument adapted to the reception of *sound*; that is to say, already knowing that sound consists in

pulses of the air, we perceive, in the structure of the ear, a suitableness to receive impressions from this species of action, and to propagate the impressions to the brain. For of what does this structure consist? An external ear (the concha), calculated, like an ear-trumpet, to catch and collect the pulses of which we have spoken; in large quadrupeds, turning to the sound, and possessing a configuration, as well as motion, evidently fitted for the office; of a tube which leads into the head, lying at the root of this outward ear, the folds and sinuses thereof tending and conducting the air towards it; of a thin membrane, like the pelt of a drum, stretched across this passage upon a bony rim; of a chain of moveable, and infinitely curious, bones, forming a communication, and the only communication that can be observed, between the membrane last mentioned and the interior channels and recesses of the skull; of cavities, similar in shape and form to wind instruments of music, being spiral or portions of circles; of the eustachian tube, like the hole in a drum, to let the air pass freely into and out of the barrel of the ear, as the covering membrane vibrates, or as the temperature may be altered: the whole labyrinth hewn out of a rock; that is, wrought into the

substance of the hardest bone of the body. This assemblage of connected parts constitutes together an apparatus, plainly enough relative to the transmission of sound, or of the impulses received from sound.

The communication within, formed by the small bones of the ear, is, to look upon, more like what we are accustomed to call machinery, than anything I am acquainted with in animal bodies. It seems evidently designed to continue towards the sensorium the tremulous motions which are excited in the membrane of the tympanum, or what is better known by the name of the "drum of the ear." The compages of bones consists of four, which are so

*a*, the incus, *b*, the malleus; *c*, the *os orbiculare*; *d*, the *stapes*.

disposed, and so hinge upon one another, as that if the membrane of the drum of the ear

vibrate, all the four are put in motion together; and, by the result of their action, work the base of that which is the last in the series, upon an aperture which it closes, and upon which it plays, and which aperture opens into the labyrinth where the nerve is distributed. This last bone of the four is called the *stapes*. The office of the drum of the ear is to spread out an extended surface capable of receiving the impressions of sound, and of being put by them into a state of vibration. The office of the stapes is to repeat these vibrations. It is a repeating frigate, stationed more within the line. From which account of its action may be understood, how the sensation of sound will be excited by anything which communicates a vibratory motion to the stapes, though not, as in all ordinary cases, through the intervention of the membrana tympani. This is done by solid bodies applied to the bones of the skull, as by a metal bar holden at one end between the teeth, and touching at the other end a tremulous body. It likewise appears to be done, in a considerable degree, by the air itself, even when the membrane of the drum of the ear is greatly damaged. Either in the natural or preternatural state of the organ, the use of the chain of bones is to propagate the impulse

in a direction towards the brain, and to propagate it with the advantage of a lever; which advantage consists in increasing the force and strength of the vibration, and at the same time diminishing the space through which it oscillates: both of which changes may augment

STRUCTURE OF THE INTERNAL EAR,  
showing the parts (described in cut p. 57) on an enlarged scale.

or facilitate the impression made on the auditory nerves.

The benefit of the eustachian tube to the organ may be made out upon known pneumatic

principles. Within the drum-head or membrane is a cavity which is called the tympanum. The eustachian tube is a slender pipe, but sufficient for the passage of air, leading from this cavity into the back part of the mouth. Now, it would not have done to have had a vacuum in this cavity; for, in that case, the pressure of the atmosphere from without would have burst the membrane which covered it. Nor would it have done to have filled the cavity with lymph or any other secretion; which would necessarily have obstructed both the vibration of the membrane and the play of the small bones. Nor, lastly, would it have done to have occupied the space with confined air, because the expansion of that air by heat, or its contraction by cold, would have distended or relaxed the covering membrane, in a degree inconsistent with the purpose which it was assigned to execute. The only remaining expedient, and that for which the eustachian tube serves, is to open to this cavity a communication with the external air. In one word; it exactly answers the purpose of the hole in a drum.

The membrana tympani itself, likewise, deserves all the examination which can be made of it. It is not found in the ears of fish;

which furnishes an additional proof of what indeed is indicated by everything about it, that it is appropriated to the action of air, or of an elastic medium. It bears an obvious resemblance to the pelt or head of a drum, from which it takes its name. It resembles also a drum-head in this principal property, that its use depends upon its tension. *Tension* is the state essential to it. Now we know that, in a drum, the pelt is carried over a hoop, and braced as occasion requires, by the means of strings attached to its circumference. In the membrane of the ear, the same purpose is provided for, more simply, but not less mechanically nor less successfully, by a different expedient, viz. by the end of a moveable bone (the handle of the malleus) pressing upon its centre.

The essential part of the organ of hearing is, of course, the special nerve; and so long as the function of this nerve is unimpaired, defects in the modifying apparatus may exist, without destroying the sense. Thus the drum may be opened, and the small bones may be removed or the eustachian tube may be closed, causing serious derangement of the function, but without entirely suppressing it. This is not the case with the eye; and the difference

is due to the coarser nature of the medium through which sound is propagated than that through which light is transmitted : moreover, sound is conducted through the solid texture of the surrounding bones. The tympanic membrane is not muscular ; but its degree of tension is regulated by two small muscles, which act upon it through the medium of the small bones to which they are attached. The labyrinth is lined by a membrane of extreme delicacy, and is partly occupied by fluid : its several component parts present an extended surface whereon the nerve of hearing is spread out ; and it is possible their peculiar form is designed to assist us in determining the direction from which a sound comes.

## CHAPTER IV.

## OF THE SUCCESSION OF PLANTS AND ANIMALS.

THE *generation* of the animal no more accounts for the contrivance of the eye or ear, than, upon the supposition stated in a preceding chapter, the production of a watch by the motion and mechanism of a former watch, would account for the skill and intention evidenced in the watch, so produced; than it would account for the disposition of the wheels, the catching of their teeth, the relation of the several parts of the works to one another, and to their common end; for the suitableness of their forms and places to their offices, for their connexion, their operation, and the useful result of that operation. I do insist most strenuously upon the correctness of this comparison; that it holds as to every mode of specific propagation; and that whatever was true of the watch, under the hypothesis above-mentioned, is true of plants and animals.

I. To begin with the fructification of plants. Can it be doubted but that the seed contains a particular organization? Whether a latent plantule with the means of temporary nutrition, or whatever else it be, it encloses an organization, suited to the germination of a new plant. Has the plant which produced the seed anything more to do with that organization, than the watch would have had to do with the structure of the watch which was produced in the course of its mechanical movement? I mean, Has it anything at all to do with the *contrivance*? The maker and contriver of one watch, when he inserted within it a mechanism suited to the production of another watch, was, in truth, the maker and contriver of that other watch. All the properties of the new watch were to be referred to his agency; the design manifested in it, to his intention; the art, to him as the artist; the collocation of each part, to his placing; the action, effect, and use, to his counsel, intelligence and workmanship. In producing it by the intervention of a former watch, he was only working by one set of tools instead of another. So it is with the plant, and the seed produced by it. Can any distinction be assigned between the two cases; between the producing watch, and the producing plant;

both passive, unconscious substances ; both, by the organization which was given to them, producing their like, without understanding or design ; both, that is, instruments ?

II. From plants we may proceed to oviparous animals ; from seeds to eggs. Now I say, that the bird has the same concern in the formation of the egg which she lays, as the plant has in that of the seed which it drops ; and no other, nor greater. The internal constitution of the egg is as much a secret to the hen, as if the hen were inanimate. Her will cannot alter it, or change a single feather of the chick. She can neither foresee nor determine of which sex her brood shall be, or how many of either : yet the thing produced shall be, from the first, very different in its make, according to the sex which it bears. So far, therefore, from adapting the means, she is not beforehand apprized of the effect. If there be concealed within that smooth shell a provision and a preparation for the production and nourishment of a new animal, they are not of her providing or preparing : if there be contrivance, it is none of hers. Although, therefore, there be the difference of life and perceptivity between the animal and the plant, it is a difference which enters not into the account. It is a foreign circumstance. It is a difference

of properties not employed. The animal function and the vegetable function are alike destitute of any design which can operate upon the form of the thing produced. The plant has no design in producing the seed, no comprehension of the nature or use of what it produces ; the bird with respect to its egg, is not above the plant with respect to its seed. Neither the one nor the other bears that sort of relation to what proceeds from them, which a joiner does to the chair which he makes. Now a cause, which bears *this* relation to the effect, is what we want, in order to account for the suitableness of means to an end, the fitness and fitting of one thing to another ; and this cause the parent plant or animal does not supply.

It is further observable concerning the propagation of plants and animals, that the apparatus employed exhibits no resemblance to the thing produced ; in this respect holding an analogy with instruments and tools of art. The filaments, antheræ, and stigmata of flowers, bear no more resemblance to the young plant, or even to the seed, which is formed by their intervention, than a chisel or a plane does to a table or chair. What then are the filaments, antheræ, and stigmata of plants, but instruments strictly so called ?

III. We may advance from animals which bring forth eggs, to animals which bring forth their young alive; and of this latter class, from the lowest to the highest; from irrational to rational life, from brutes to the human species; without perceiving, as we proceed, any alteration whatever in the terms of the comparison. The rational animal does not produce its offspring with more certainty or success than the irrational animal: a man than a quadruped, a quadruped than a bird; nor (for we may follow the gradation through its whole scale) a bird than a plant; nor a plant than a watch, a piece of dead mechanism, would do, upon the supposition which has already so often been repeated. Rationality therefore has nothing to do in the business. If an account must be given of the contrivance which we observe; if it be demanded, whence arose either the contrivance by which the young animal is produced, or the contrivance manifested in the young animal itself, it is not from the reason of the parent that any such account can be drawn. He is the cause of his offspring, in the same sense as that in which a gardener is the cause of the tulip which grows upon his parterre, and in no other. We admire the flower; we examine the plant; we perceive the conduciveness of many of its parts to their

end and office; we observe a provision for its nourishment, growth, protection, and fecundity; but we never think of the gardener in all this. We attribute nothing of this to his agency; yet it may still be true, that without the gardener we should not have had the tulip; just so it is with the succession of animals even of the highest order. For the contrivance discovered in the structure of the thing produced, we want a contriver. The parent is not that contriver. His consciousness decides that question. He is in total ignorance why that which is produced took its present form rather than any other. It is for him only to be astonished by the effect. We can no more look therefore to the intelligence of the parent animal for what we are in search of, a cause of relation, and of subserviency of parts to their use, which relation and subserviency we see in the procreated body, than we can refer the internal conformation of an acorn to the intelligence of the oak from which it dropped, or the structure of the watch to the intelligence of the watch which produced it; there being no difference, as far as argument is concerned, between an intelligence which is not exerted, and an intelligence which does not exist.

## CHAPTER V.

## APPLICATION OF THE ARGUMENT, CONTINUED.

EVERY observation which was made in our first chapter concerning the watch, may be repeated with strict propriety concerning the eye; concerning animals; concerning plants; concerning, indeed, all the organized parts of the works of nature. As,—

I. When we are inquiring simply after the *existence* of an intelligent Creator, imperfection, inaccuracy, liability to disorder, occasional irregularities, may subsist in a considerable degree, without inducing any doubt into the question; just as a watch may frequently go wrong, seldom perhaps exactly right, may be faulty in some parts, defective in some, without the smallest ground of suspicion from thence arising that it was not a watch; not made; or not made for the purpose ascribed to it. When faults are pointed out, and when a question is

started concerning the skill of the artist, or dexterity with which the work is executed, then indeed, in order to defend these qualities from accusation, we must be able, either to expose some intractableness and imperfection in the materials, or point out some invincible difficulty in the execution, into which imperfection and difficulty the matter of complaint may be resolved; or if we cannot do this, we must adduce such specimens of consummate art and contrivance, proceeding from the same hand, as may convince the inquirer of the existence, in the case before him, of impediments like those which we have mentioned, although, what from the nature of the case is very likely to happen, they be unknown and unperceived by him. This we must do in order to vindicate the artist's skill, or, at least, the perfection of it; as we must also judge of his intention, and of the provisions employed in fulfilling that intention, not from an instance in which they fail, but from the great plurality of instances in which they succeed. But, after all, these are different questions from the question of the artist's existence: or, which is the same, whether the thing before us be a work of art or not: and the questions ought always to be kept separate in the mind. So likewise it is in the works of

nature. Irregularities and imperfections are of little or no weight in the consideration, when that consideration relates simply to the existence of a Creator. When the argument respects His attributes, they are of weight; but are then to be taken in conjunction (the attention is not to rest upon them, but they are to be taken in conjunction) with the unexceptionable evidence which we possess, of skill, power, and benevolence, displayed in other instances; which evidences may, in strength, number, and variety, be such, and may so overpower apparent blemishes, as to induce us, upon the most reasonable ground, to believe that these last ought to be referred to some cause, though we be ignorant of it, other than defect of knowledge or of benevolence in the author.

II. There may be also parts of plants and animals, as there were supposed to be of the watch, of which, in some instances the operation, in others the use, is unknown. These form different cases; for the operation may be unknown, yet the use be certain. This is exemplified rather by the past history than the present state of physiology. The utility of the lungs, and the necessity of breathing the atmospheric air, were known long before it was ascertained that carbon was thereby removed

from the blood in the form of carbonic acid, and oxygen introduced in its place. The same may be said of the lymphatic system, the agency of which, in the animal economy, is now well understood. The spleen, again, was formerly considered to be an useless organ, but modern investigation has shown that it is importantly concerned in the latest stage of the conversion of aliment into circulating blood. Instances of the former kind, namely, in which we cannot explain the operation, are more numerous ; for they will be so in proportion to our ignorance. They will be more or fewer to different persons, and in different stages of science. Every improvement of knowledge diminishes their number. There is hardly, perhaps, a year passes, that does not, in the works of nature, bring some operation, or some mode of operation, to light, which was before undiscovered,—probably unsuspected. Instances of the second kind, namely, where the part appears to be totally useless, I believe to be extremely rare ; compared with the number of those, of which the use is evident, they are beneath any assignable proportion ; and have latterly become quite insignificant. But to such cases, even were they fully made out, may be applied the consideration which we suggested concerning the watch,

---

viz. that these superfluous parts do not negative the reasoning which we instituted concerning those parts which are useful, and of which we know the use: the indication of contrivance, with respect to them, remains as it was before. Indeed, the only parts to which we can venture to apply the term "superfluous," in the animal frame, are those which exist in a rudimentary form, and are typical of that unity of structure which pervades the development of organized beings.

III. One atheistic way of replying to our observations upon the works of nature, and to the proofs of a Deity which we think that we perceive in them, is to tell us, that all which we see must necessarily have had some form, and that it might as well be its present form as any other. Let us now apply this answer to the eye, as we did before to the watch. Something or other must have occupied that place in the animal's head: must have filled up, we will say, that socket: we will say also, that it must have been of that sort of substance which we call animal substance, as flesh, bone, membrane, cartilage, &c. But that it should have been an *eye*, knowing as we do what an eye comprehends,—viz. that it should have consisted, first, of a series of transparent lenses (very different, by-the-bye, even in their substance, from

the opaque materials of which the rest of the body is, in general at least, composed ; and with which the whole of its surface, this single portion of it excepted, is covered) : secondly, of a black cloth or canvas (the only membrane of the body which is black) spread out behind these lenses, so as to receive the image formed by pencils of light transmitted through them ; and placed at the precise geometrical distance at which, and at which alone, a distinct image could be formed, namely, at the concourse of the refracted rays : thirdly, of a large nerve communicating between this membrane and the brain ; without which the action of light upon the membrane, however modified by the organ, would be lost to the purposes of sensation :—that this fortunate conformation of parts should have been the lot, not of one individual out of many thousand individuals, like the great prize in a lottery, or like some singularity in nature, but the happy chance of a whole species ; nor of one species out of many thousand species, with which we are acquainted, but of by far the greatest number of all that exist : and that under varieties, not casual or capricious, but bearing marks of being suited to their respective exigencies :—that all this should have taken place, merely because something must have occupied those points in every animal's forehead ;—or, that

all this should be thought to be accounted for, by the short answer, "that whatever was there, must have had some form or other," is too absurd to be made more so by any augmentation. We are not contented with this answer; we find no satisfaction in it, by way of accounting for appearances of organization far short of those of the eye, such as we observe in fossil shells and bones, or other substances which bear the vestiges of animal or vegetable recrements, but which, either in respect of utility or of the situation in which they are discovered, may seem accidental enough. It is no way of accounting even for these things, to say that the stone, for instance, which is shown to us (supposing the question to be concerning a petrification) must have contained some internal conformation or other. Nor does it mend the answer to add, with respect to the singularity of the conformation, that, after the event, it is no longer to be computed what the chances were against it. This is always to be computed, when the question is, whether a useful or imitative conformation be the produce of chance, or not: I desire no greater certainty in reasoning, than that by which chance is excluded from the present disposition of the natural world. Universal experience is against it. What does chance ever do for us? In the human body, for instance, chance, i. e. the operation of

causes without apparent design, may produce a wen, a wart, a mole, a pimple, but never an eye. Amongst inanimate substances, a clod, a pebble, a liquid drop might be; but never was a watch, a telescope, an organized body of any kind, answering a valuable purpose by a complicated mechanism; the effect of so-called chance. In no assignable instance hath such a thing existed without evident intention somewhere. Strictly speaking, "chance" cannot be said to determine anything. When we employ the word in the above sense, it can only mean that we are ignorant how any given effect is produced, that we are incapable of influencing that effect, and that we fail to trace design in its production.

IV. There is another answer, which has the same effect as the resolving of things into chance; which answer would persuade us to believe, that the eye, the animal to which it belongs, every other animal, every plant, indeed every organized body which we see, are only so many out of the possible varieties and combinations of being, which the lapse of infinite ages has brought into existence; that the present world is the relict of that variety; millions of other bodily forms and other species having perished, being by the defect of their constitution incapable of preservation, or of continuance by generation. Geo-

logy indubitably demonstrates that many varieties of animals and plants have existed and perished in regular succession, to be followed by others of a higher organization. But the same observations teach us that these successive changes were determined by definite laws, arranged according to a definite plan, and adapted to the existing condition of the earth's surface. There was clearly no element of so-called chance in the production of this progressive development of animal and vegetable life.

V. To the marks of contrivance discoverable in animal bodies, and to the argument deduced from them, in proof of design and of a designing Creator, this turn is sometimes attempted to be given, namely, that the parts were not intended for the use, but that the use arose out of the parts. This distinction is intelligible. A cabinet-maker rubs his mahogany with fish-skin ; yet it would be too much to assert that the skin of the dog-fish was made rough and granulated on purpose for the polishing of wood, and the use of cabinet-makers. Therefore the distinction is intelligible. But I think that there is very little place for it in the works of nature. When roundly and generally affirmed of them, as it hath sometimes been, it amounts to such another stretch of assertion, as it would

be to say, that all the implements of the cabinet-maker's workshop, as well as his fish-skin, were substances accidentally configurated, which he had picked up, and converted to his use ; that his adzes, saws, planes, and gimlets, were not made, as we suppose, to hew, cut, smooth, shape out, or bore wood with ; but that, these things being made, no matter with what design, or whether with any, the cabinet-maker perceived that they were applicable to his purpose, and turned them to account.

But, again. So far as this solution is attempted to be applied to those parts of animals, the action of which does not depend upon the will of the animal, it is fraught with still more evident absurdity. Is it possible to believe that the eye was formed without any regard to vision ; that it was the animal itself which found out that, though formed with no such intention, it would serve to see with ; and that the use of the eye, as an organ of sight, resulted from this discovery and the animal's application of it ? The same question may be asked of the ear ; the same of all the senses. None of the senses fundamentally depend upon the election of the animal ; consequently, neither upon his sagacity nor his experience. It is the impression which objects make upon them, that

---

constitutes their use. Under that impression he is passive. He may bring objects to the sense, or within its reach ; he may select these objects : but over the impression itself he has no power, or very little ; and that properly is the sense.

Secondly ; there are many parts of animal bodies which seem to depend upon the will of the animal in a greater degree than the senses do, and yet with respect to which this solution is equally unsatisfactory. If we apply the solution to the human body, for instance, it forms itself into questions, upon which no reasonable mind can doubt ; such as, whether the teeth were made expressly for the mastication of food, the feet for walking, the hands for holding ? or whether, these things being as they are, being in fact in the animal's possession, his own ingenuity taught him that they were convertible to these purposes, though no such purposes were contemplated in their formation ?

All that there is of the appearance of reason in this way of considering the subject is, that in some cases, it may be urged, the organization seems to determine the habits of the animal, and its choice to a particular mode of life ; which, in a certain sense, may be called "the

use arising out of the part." Now to all the instances, in which there is any place for this suggestion, it may be replied, that the organization determines the animal to habits beneficial and salutary to itself; and that this effect would not be seen so regularly to follow, if the several organizations did not bear a concerted and contrived relation to the substance by which the animal was surrounded. They would, otherwise, be capacities without objects; powers without employment. The web-foot determines, you say, the duck to swim; but what would that avail, if there were no water to swim in? The strong, hooked bill and sharp talons of one species of bird, determine it to prey upon animals; the soft, straight bill and weak claws of another species, determine it to pick up seeds; but neither determination could take effect in providing for the sustenance of the birds, if animal bodies and vegetable seeds did not lie within their reach. The peculiar conformation of the bill, and tongue, and claws of the woodpecker, determines that bird to search for his food amongst the insects lodged behind the bark, or in the wood, of decayed trees; but what would this profit him, if there were no trees, no decayed trees, no insects lodged under their bark, or in their trunk?

---

The proboscis with which the bee is furnished determines him to seek for honey ; but what would that signify, if flowers supplied none ? Faculties thrown down upon animals at random, and without reference to the objects amidst which they are placed, would not produce to them the services and benefits which we see ; and if there be that reference, then there is intention.

The modern views of development, or evolution, do not make void the argument, as it is shown elsewhere. (See Introduction.) The operation of a general law, in the production of many and diverse results, must enhance, in our estimation, the Power and Wisdom of the Designer.

Lastly ; the solution fails entirely when applied to plants. The parts of plants answer their uses, without any concurrence from the will or choice of the plant.

VI. Others have chosen to refer everything to a *principle of order* in nature. A principle of order is the word ; but what is meant by a principle of order, as different from an intelligent Creator, has not been explained either by definition or example ; and, without such explanation, it should seem to be a mere substitution of words for reasons, names for causes. Order itself is only the adaptation of means to an

end : a principle of order, therefore, can only signify the mind and intention which so adapts them. Or, were it capable of being explained in any other sense, is there any experience, any analogy, to sustain it? Was a watch ever produced by a principle of order? and why might not a watch be so produced as well as an eye?

Furthermore, a principle of order, acting blindly and without choice, is negatived by the observation that order is not universal; which it would be, if it issued from a constant and necessary principle: nor indiscriminate, which it would be, if it issued from an unintelligent principle. Where order is wanted, there we find it; where order is not wanted, i. e., where, if it prevailed, it would be useless, there we do not find it. In the structure of the eye (for we adhere to our example), in the figure and position of its several parts, the most exact order is maintained. In the forms of rocks and mountains, in the lines which bound the coasts of continents and islands, in the shape of bays and promontories, no order whatever is perceived, because it would have been superfluous. No useful purpose would have arisen from moulding rocks and mountains into regular solids, bounding the channel of the ocean.

by geometrical curves; or from the map of the world resembling a table of diagrams in Euclid's Elements, or Simpson's Conic Sections.

Nevertheless, it is not to be denied that a principle of order pervades creation; and this is so as a necessary result of the laws by and through which it has pleased the Creator to work. The operation of a law is not always apparent in all its bearings and relations, and thence the seeming disorder and exceptional derangement of plan, which is, in reality, due to our limited knowledge and circumscribed sphere of observation. As these expand we are enabled to reconcile inconsistencies, and to include exceptional deviations in that principle of order, which was previously misunderstood, because only partially perceived or apprehended.

VII. Lastly; the confidence which we place in our observations upon the works of nature; in the marks which we discover of contrivance, choice, and design; and in our reasoning upon the proofs afforded us; ought not to be shaken, as it is sometimes attempted to be done, by bringing forward to our view our own ignorance, or rather the general imperfection of our knowledge of nature. Nor, in many cases,

ought this consideration to affect us, even when it respects some parts of the subject immediately under our notice. True fortitude of understanding consists in not suffering what we know, to be disturbed by what we do not know. If we perceive a useful end, and means adapted to that end, we perceive enough for our conclusion. If these things be clear, no matter what is obscure; the argument is finished. For instance: if the utility of vision to the animal which enjoys it, and the adaptation of the *eye* to this office, be evident and certain (and I can mention nothing which is more so), ought it to prejudice the inference which we draw from these premisses, if we could not explain the use of the spleen? Nay, more: if there be parts of the eye, viz. the cornea, the crystalline, the retina, in their substance, figure, and position, manifestly suited to the formation of an image by the refraction of rays of light, at least as manifestly as the glasses and tubes of a dioptric telescope are suited to that purpose; it concerns not the proof which these afford of design, and of a designer, that there may perhaps be other parts, certain muscles for instance, or nerves in the same eye, of the agency or effect of which we can give no account; any more than we should be inclined to doubt, or ought to doubt,

about the construction of a telescope, viz. for what purpose it was constructed, or whether it were constructed at all, because there belonged to it certain screws and pins, the use or action of which we did not comprehend. I take it to be a general way of infusing doubts and scruples into the mind, to recur to its own ignorance, its own imbecility; to tell us that upon these subjects we know little, that little imperfectly; or rather, that we know nothing properly about the matter. These suggestions so fall in with our consciousness, as sometimes to produce a general distrust of our faculties and our conclusions. But this is an unfounded jealousy. The uncertainty of one thing does not necessarily affect the certainty of another thing. Our ignorance of many points need not suspend our assurance of a few. Before we yield, in any particular instance, to the scepticism which this sort of insinuation would induce, we ought accurately to ascertain whether our ignorance or doubt concern those precise points upon which our conclusion rests. Other points are nothing. Our ignorance of other points may be of no consequence to these, though they ~~are~~ points, in various respects, of great importance; and our experience of past discoveries, and especially the vast additions recently made to

our knowledge of the functions of various organs in the animal body, may reasonably induce us to hope that this source of obscurity will cease to be a stumbling-block. A just reasoner removes from his consideration, not only what he knows, but what he does not know, touching matters not strictly connected with his argument, i. e. not forming the very steps of his deduction : beyond these, his knowledge and his ignorance are alike relative.

## CHAPTER VI.

## THE ARGUMENT CUMULATIVE.

WERE there no example in the world of contrivance, except that of the *eye*, it would be alone sufficient to support the conclusion which we draw from it, as to the necessity of an intelligent Creator. It could never be got rid of; because it could not be accounted for by any other supposition, which did not contradict all the principles we possess of knowledge; the principles, according to which things do, as often as they can be brought to the test of experience, turn out to be true or false. Its coats and humours, constructed, as the lenses of a telescope are constructed, for the refraction of rays of light to a point, which forms the proper action of the organ; the provision in its muscles and tendons for turning its pupil to the object, similar to that which is given to the telescope by screws, and upon which power of

---

direction in the eye, the exercise of its office as an optical instrument depends; the further provision for its defence, for its constant lubricity and moisture, which we see in its socket and its lids, in its gland for the secretion of the matter of tears, its outlet or communication with the nose for carrying off the liquid after the eye is washed with it; these provisions compose altogether an apparatus, a system of parts, a preparation of means, so manifest in their design, so exquisite in their contrivance, so successful in their issue, so precious, and so infinitely beneficial in their use, as, in my opinion, to bear down all doubt that can be raised upon the subject. And what I wish, under the title of the present chapter, to observe is, that if other parts of nature were inaccessible to our inquiries, or even if other parts of nature presented nothing to our examination but disorder and confusion, the validity of this example would remain the same. If there were but one watch in the world, it would not be less certain that it had a maker. If we had never in our lives seen any but one single kind of hydraulic machine, yet, if of that one kind we understood the mechanism and use, we should be as perfectly assured that it proceeded from the hand, and thought, and skill of a workman,

as if we visited a museum of the arts, and saw collected there twenty different kinds of machines for drawing water, or a thousand different kinds for other purposes. Of this point each machine is a proof, independently of all the rest. So it is with the evidences of a Divine agency. The proof is not a conclusion which lies at the end of a chain of reasoning, of which chain each instance of contrivance is only a link, and of which, if one link fail, the whole falls; but it is an argument separately supplied by every separate example. An error in stating an example affects only that example. The argument is cumulative, in the fullest sense of that term. The eye proves it without the ear; the ear without the eye. The proof in each example is complete; for when the design of the part, and the conduciveness of its structure to that design are shown, the mind may set itself at rest; no future consideration can detract anything from the force of the example.

## CHAPTER VII.

### OF THE MECHANICAL AND IMMECHANICAL PARTS AND FUNCTIONS OF ANIMALS AND VEGETABLES.

IT is not that *every* part of an animal or vegetable has not proceeded from a contriving mind ; or that every part is not constructed with a view to its proper end and purpose, according to the laws belonging to and governing the substance or the action made use of in that part ; or that each part is not so constructed as to effectuate its purpose whilst it operates according to these laws ; but it is because these laws themselves are not in all cases equally understood ; or, what amounts to nearly the same thing, are not equally exemplified in more simple processes, and more simple machines ; that we lay down the distinction, here proposed, between the mechanical parts and other parts of animals and vegetables.

For instance : the principle of muscular

motion, viz. upon what cause the swelling of the belly of the muscle, and consequent contraction of its tendons, either by an act of the will, or by involuntary irritation, depends, is wholly unknown to us. The substance employed, whether it be fluid, gaseous, elastic, electrical, or none of these, or nothing resembling these, is also unknown to us: of course, the laws belonging to that substance, and which regulate its action are unknown to us. We see nothing similar to this contraction in any machine which we can make, or any process which we can execute. So far (it is confessed) we are in ignorance, but no further. This power and principle, from whatever cause it proceeds, being assumed, the collocation of the fibres to receive the principle, the disposition of the muscles for the use and application of the power, is mechanical; and is as intelligible as the adjustment of the wires and strings by which a puppet is moved. We see, therefore, as far as respects the subject before us, what is not mechanical in the animal frame, and what is. The nervous influence (for we are often obliged to give names to things which we know little about)—I say the nervous influence, by which the belly or middle of the muscle is shortened and swelled, is not mechanical. The utility of the effect we perceive; the

means, or the preparation of means, by which it is produced, we do not. But obscurity as to the origin of muscular motion brings no doubtfulness into our observations, upon the sequel of the process. Which observations relate, *1st*, to the constitution of the muscle ; in consequence of which constitution, the swelling and shortening of the belly or middle part is necessarily and mechanically followed by a traction of the tendons : *2ndly*, to the number and variety of the muscles, and the corresponding number and variety of useful powers which they supply to the animal ; which is astonishingly great : *3rdly*, to the judicious (if we may be permitted to use that term, in speaking of the author or of the works of nature), to the wise and well-contrived disposition of each muscle for its specific purpose ; for moving the joint this way, and that way, and the other way ; for pulling and drawing the part to which it is attached, in a determinate and particular direction ; which is a mechanical operation, exemplified in a multitude of instances. To mention only one : The tendon of the trochlear muscle of the eye, to the end that it may draw in the line required, is passed through a cartilaginous ring, at which it is reverted, exactly in the same manner as a rope in a ship is carried over a block or round a

stay, in order to make it pull in the direction which is wanted. All this, as we have said is mechanical; and is as accessible to inspection, as capable of being ascertained, as the mechanism of the automaton in the Strand. Suppose the automaton to be put in motion by a magnet (which is probable), it will supply us with a comparison very apt for our present purpose. Of the nature of the magnetic influence we know perhaps as little as we do of the nervous fluid, although the phenomena attending the agency of each have been of late years more carefully studied, and are now better understood. But, magnetic attraction being assumed (it signifies nothing from what cause it proceeds), we can trace, or there can be pointed out to us, with perfect clearness and certainty, the mechanism, viz. the steel bars, the wheels, the joints, the wires, by which the motion so much admired is communicated to the fingers of the image: and to make any obscurity, or difficulty, or controversy in the doctrine of magnetism, an objection to our knowledge or our certainty concerning the contrivance, or the marks of contrivance, displayed in the automaton, would be exactly the same thing, as it is to make our ignorance (which we acknowledge) of the cause of nervous agency, or even of the substance and structure of the

nerves themselves, a ground of question or suspicion as to the reasoning which we institute concerning the mechanical part of our frame. That an animal is a machine, is a proposition neither correctly true nor wholly false. The distinction which we have been discussing will serve to show how far the comparison, which this expression implies, holds; and wherein it fails. And whether the distinction be thought of importance or not, it is certainly of importance to remember, that there is neither truth nor justice in endeavouring to bring a cloud over our understandings, or a distrust into our reasonings upon this subject, by suggesting that we have but imperfect knowledge of voluntary motion, of irritability, of the principle of life, of sensation, of animal heat, upon all which the animal functions depend; for, our ignorance of these parts of the animal frame concerns not at all our knowledge of the mechanical parts of the same frame. I contend, therefore, that there is mechanism in animals; that this mechanism is as properly such, as it is in machines made by art; that this mechanism is intelligible and certain; that it is not the less so, because it often begins or terminates with something which is not mechanical; that whenever it is intelligible and certain, it demonstrates inten-

tion and contrivance, as well in the works of nature as in those of art; and that it is the best demonstration which either can afford.

But whilst I contend for these propositions, I do not exclude myself from asserting, that there may be, and that there are, other cases in which, although we cannot exhibit mechanism, or prove indeed that mechanism is employed, we want not sufficient evidence to conduct us to the same conclusion.

There is what may be called the *chemical* part of our frame; of which, by reason of the imperfection of our chemistry, we can attain to no distinct knowledge; I mean, not to a knowledge, either in degree or kind, similar to that which we possess of the mechanical part of our frame. It does not, therefore, afford the same species of argument as that which mechanism affords; and yet it may afford an argument in a high degree satisfactory. The *gastric juice*, or the liquor which chiefly digests the food in the stomachs of animals, is of this class. Of all menstrua it is the most active, the most universal. In the human stomach, for instance, consider what a variety of strange substances, and how widely different from one another are, in a few hours, reduced to a uniform pulp, milk, or mucilage. The juices seize upon everything,

dissolve the texture of almost everything that comes in their way. The flesh of perhaps all animals; the seeds and fruits of the greatest number of plants; the roots, and stalks, and leaves of many, hard and tough as they are, yield to their powerful pervasion. The changes wrought are different from those by any chemical solution which we can produce; for all substances, whether animal or vegetable, fat or lean, are dissolved by digestion, so far as nutriment can be obtained from them. Consider moreover that the chief digestive fluid, so powerful in its operation, is nevertheless mild and bland, and almost as inoffensive to the touch or taste, as saliva or gum-water. Consider, I say, these several properties of the digestive organ, and of the juice with which it is supplied, or rather with which it is made to supply itself, and the ingredients of which this fluid is composed, and you will confess it to be entitled to a name, which it has sometimes received, that of "the chemical wonder of animal nature."

Another most subtle and curious function of animal bodies is *secretion*. This function is exceedingly important and diversified in its effects, but obscure in its process, though its apparatus is comparatively simple. The importance of the secretory organs is but too well attested by the

diseases, which an excessive, a deficient, or a vitiated secretion is almost sure of producing. A single secretion being wrong is enough to make life miserable, or sometimes to destroy it. Nor is the variety less than the importance. From one and the same blood (I speak of the human body) about twenty different fluids are separated ; in their sensible properties, in taste, smell, colour and consistency, the most unlike one another that is possible : thick, thin, salt, bitter, sweet : and, if from our own we pass to other species of animals, we find amongst their secretions not only the most various, but the most opposite properties ; the most nutritious aliment, the deadliest poison ; the sweetest perfumes, the most foetid odours. Of these the greater part, as the gastric juice, the saliva, the bile, the slippery mucilage which lubricates the joints, the tears which moisten the eye, the wax which defends the ear, are, after they are secreted, made use of in the animal economy ; are evidently subservient, and are actually contributing, to the utilities of the animal itself. Other fluids seem to be separated only to be rejected. That this also is necessary for the removal of deleterious or superfluous materia from the system, is shown by the consequence of the separation being long suspended ; which

consequence is disease and death. Akin to secretion, if not the same thing, is assimilation, by which one and the same blood is converted into bone, muscle or flesh, nerves, membranes, tendons ; things as different as the wood and iron, canvas and cordage, of which a ship with its furniture is composed. We have no operation of art wherewith exactly to compare all this, for no other reason perhaps than that all operations of art are exceeded by it. No chemical elections, no chemical analysis or resolution of a substance into its constituent parts, no mechanical sifting or division, that we are acquainted with, in perfection or variety come up to animal secretion. Nevertheless, the apparatus and process are obscure ; not to say absolutely concealed from our inquiries. Of late years we have been able to discern something of the constitution of a gland by unravelling its structure. In the kidneys of animals, we can trace the supplying artery dividing itself into an infinite number of branches ; their extremities everywhere terminating in little saccules, from which the delicate tubes containing the secretion originate. These tubes open on the surface of several small cones, which are surrounded by membranous caps ; and from these caps the secretion is conducted by large tubes into a receptacle called the *pelvis* of the kidney,

and thence by a single canal on each side, called the ureter, to the bladder : the secreted fluid is thus continually oozing into its receptacle. This is all we know of the mechanism of a gland, even in the case in which it seems most capable of being investigated. Yet to pronounce that we know nothing of animal secretion, or nothing satisfactorily, and with that concise remark to dismiss the article from our argument, would be to dispose of the subject very hastily and very irrationally. For the purpose which we want, that of evincing intention, we know a great deal. And what we know is this. We see the blood carried by a pipe, conduit, or tube *to* the gland. We see an organized apparatus, be its construction or action what it will, which we call that gland. We see the blood, or part of the blood, after it has passed through and undergone the action of the gland, coming *from* it by an emulgent vein, i. e. by another pipe or conduit. And we see also at the same time a new and specific fluid issuing from the same gland by its excretory duct, i. e. by a third pipe or conduit; which new fluid is, in the case of some glands, discharged out of the body, in more cases retained within it, there to execute some important and intelligible office. Now supposing, or admitting, that we know

nothing of the proper internal constitution of a gland, or of the mode of its acting upon the blood ; then our situation is precisely like that of an unmechanical looker-on, who stands by a stocking-loom, a corn-mill, a carding-machine, or a threshing-machine, at work, the fabric and mechanism of which, as well as all that passes within, is hidden from his sight by the outside case ; or, if seen, would be too complicated for his uninformed, uninstructed understanding to comprehend. And what is that situation ? This spectator, ignorant as he is, sees at one end a material enter the machine, as unground grain the mill, raw cotton the carding-machine, sheaves of unthreshed corn the threshing-machine ; and when he casts his eye to the other end of the apparatus, he sees the material issuing from it in a new state ; and, what is more, in a state manifestly adapted to future uses ; the grain, in meal fit for the making of bread ; the wool, in rovings ready for spinning into threads ; the sheaf, in corn dressed for the mill. Is it necessary that this man, in order to be convinced that design, that intention, that contrivance has been employed about the machine, should be allowed to pull it to pieces ; should be enabled to examine the parts separately ; explore their action upon one another,

or their operation, whether simultaneous or successive, upon the machinery which is presented to them? He may long to do this to gratify his curiosity; he may desire to do it to improve his theoretic knowledge; or he may have a more substantial reason for requesting it, if he happen, instead of a common visitor, to be a mill-wright by profession, or a person sometimes called in to repair such-like machines when out of order; but, for the purpose of ascertaining the existence of counsel and design in the formation of the machine, he wants no such intromission or privity. What he sees is sufficient. The effect upon the material, the change produced in it, the utility of that change for future applications, abundantly testify, be the concealed part of the machine or of its construction what it will, the hand and agency of a contriver.

If any confirmation were wanting to the evidence which the animal secretions afford of design, it may be derived, as has been already hinted, from their variety, and from their appropriation to their place and use. They all come from the same blood: they are all drawn off by glands: yet the produce is very different, and the difference exactly adapted to the work which is to be done, or the end to be answered. No

account can be given of this, without resorting to special purpose and appointment. Why, for instance, is the saliva, which is diffused over the seat of taste, insipid, whilst so many others of the secretions, the urine, the tears, and the sweat, are salt? Why does the gland within the ear separate a viscid substance, which defends that passage; the gland in the upper angle of the eye, a thin brine, which washes the ball? Why is the synovia of the joints mucilaginous; the bile bitter, stimulating, and soapy? Why does the juice which flows into the stomach contain powers which make that bowel the great laboratory, as it is by its situation the recipient, of the materials of future nutrition? These are all fair questions; and no answer can be given to them, but what calls in intelligence and intention.

It should, however, be observed that more recent researches in animal chemistry, and in the microscopic anatomy of structures composing the animal fabric, have explained much which formerly was a mystery. This remark applies, in the present place, to the action of the gastric juice and its chemical constitution, which have been successfully studied, and made the subject of many carefully conducted experiments: also to the structure and functions of glands. But why one gland should produce one kind of

secretion, and another a fluid of an entirely different character, remains as great a mystery as ever. The same remark applies to the repair of tissues after injury; e. g. the union of a broken bone by the deposit of new bone. The vessels of each gland and texture are endowed with a special property of selecting the required material, whether for use or for abstraction; but on what physical or chemical agency this property depends is still unintelligible to us.

My object in the present chapter has been to teach three things: first, that it is a mistake to suppose that, in reasoning from the appearances of nature, the imperfection of our knowledge proportionably affects the certainty of our conclusion; for in many cases it does not affect it at all; secondly, that the different parts of the animal frame may be classed and distributed, according to the degree of exactness with which we can compare them with works of art; thirdly, that the *mechanical* parts of our frame, or those in which this comparison is most complete, although constituting, probably, the coarsest portions of nature's workmanship, are the most proper, because the most readily intelligible, to be alleged as proofs and specimens of design.

## CHAPTER VIII.

OF MECHANICAL ARRANGEMENT IN THE HUMAN  
FRAME.

WE proceed, therefore, to propose certain examples taken out of this class; making choice of such as, amongst those which have come to our knowledge, appear to be the most striking, and the best understood; but obliged, perhaps, to postpone both these recommendations to a third; that of the example being capable of explanation without plates or figures, or technical language.

## OF THE BONES.

I.—I challenge any man to produce, in the joints and pivots of the most complicated or the most flexible machine that was ever contrived, a construction more artificial, or more evidently artificial, than that which is seen in the vertebræ of the *human neck*.—Two things were to be

## 1. UPPER VIEW OF THE ATLAS VERTEBRA.

*a*, hole for the passage of the spinal marrow; *b b*, the surfaces on which the skull works; *c*, portion of the spinal hole, through which the dental or toothlike process of the dental vertebra passes, and in which situation it is fixed by a ligament which crosses it in the direction of the dotted line.

## 2. LOWER VIEW OF THE ATLAS VERTEBRA.

*a c* refer to the same parts as in fig. 1; *b b*, surfaces against which the dental vertebra works.

## 3. UPPER VIEW OF THE SECOND OR DENTAL VERTEBRA.

*a*, spinal hole; *b b*, the surfaces on which the first vertebra rests; *d*, the dental process.

## 4. PROFILE OF THE DENTAL VERTEBRA.

5. ATLAS AND DENTAL VERTEBRA,  
joined together in their natural positions.

done. The head was to have the power of bending forward and backward, as in the act of nodding, stooping, looking upward or downward; and, at the same time, of turning itself round upon the body to a certain extent, the quadrant we will say, or rather, perhaps, a hundred-and-twenty degrees of a circle. For these two purposes, two distinct contrivances are employed: First, the head rests immediately upon the uppermost of the vertebræ, and is united to it by a double joint; upon which joint the head plays freely forward and backward, and from side to side, as far either way as is necessary, or as the ligaments allow; which was the first thing required.—But then the rotatory motion is unprovided for: Therefore, secondly, to make the head capable of this, a further mechanism is introduced; not between the head and the uppermost bone of the neck, where the other joint is, but between that bone, and the bone next underneath it. It is a mechanism resembling the axle of a wheel. This second, or uppermost bone but one, has what anatomists call a process, viz. a projection, somewhat similar, in size and shape, to a large eye-tooth; which tooth, entering a corresponding socket (completed by ligament), in the bone above it, forms a pivot or axle, upon which that upper

bone, together with the head which it supports, turns freely in a circle; and as far in the circle as the attached ligaments, specially designed to check those movements, permit the head to turn. Thus are both motions perfect, without interfering with each other. When we nod the head we use the double joint, which lies between the head and the first bone of the neck. When we turn the head round, we use the pivot joint, which runs between the first bone of the neck and the second. We see the same contrivance, and the same principle, employed in the frame or mounting of a telescope. It is occasionally requisite, that the object-end of the instrument be moved up and down as well as horizontally or equatorially. For the vertical motion, there is a hinge upon which the telescope plays; for the horizontal or equatorial motion, an axis upon which the telescope and the hinge turn round together. And this is exactly the mechanism which is applied to the motion of the head: nor will any one here doubt of the existence of counsel and design, except it be by that debility of mind, which can trust to its own reasonings in nothing.

We may add that it was, on another account also, expedient that the motion of the head backward and forward should be performed upon

the upper surface of the first vertebra: for, if the first vertebra itself had bent forward, it would have brought the spinal marrow, at the very beginning of its course, upon the point of the tooth.

II.—Another mechanical contrivance, not unlike the last in its object, but different and original in its means, is seen in what anatomists call the *fore-arm*; that is, in the arm between the elbow and the wrist. Here, for the perfect use of the limb, two motions are wanted; a motion by which the elbow is bent and straightened; and a rotatory motion, by which the palm of the hand, as occasion requires, may be turned upward or downward.

BONES OF FORE-ARM.

Bones of the right fore-arm, showing their points of contrast, and how they are joined together.

How is this managed? The fore-arm consists of two bones which lie side by side, and are connected with each other by joints at the elbow and wrist; both are also connected with the upper-arm or humerus above, and with the wrist-bones below. One of these two bones—the ulna—is much larger than the

other—the radius—at the upper end, forming with the upper arm-bone a hinge joint, which admits of the elbow being straightened ; and the radius simply follows these movements. But at the lower end the size of the bones is reversed, the radius being the larger, and forming with the wrist-bones the wrist-joint, almost to the exclusion of the ulna ; this joint allows of the hand being bent forwards or backwards, and from side to side. But if the movements of the fore-arm were limited to those described, the motion of the hand would be so seriously curtailed as to render it for many purposes useless. Therefore there are other arrangements superadded, by which one bone, the radius, is permitted to roll round the other, the ulna; and for this purpose the two bones are jointed together both above and below ; and herein is the explanation of the ulna, or fixed bone as regards the rotatory movements, being the chief bone at the elbow ; and the radius or moveable bone being the larger and more important at the wrist, because it has to carry the hand with it when it revolves around the ulna. A single bone in the fore-arm, with a ball and socket joint at the elbow ; which admits of motion in all directions, might, in some degree, have answered the purpose of both moving the arm and turning the hand. But how much

SPINAL COLUMN.

Section of spinal column, showing structure of vertebræ and canal. *c1*, 1st cervical vertebra; *d1*, 1st dorsal; *l1*, 1st lumbar; *s*, sacrum; *co*, coccyx; *a*, body of vertebra; *b*, spinous process; *c*, canal.

better it is accomplished by the present mechanism any person may convince himself, who puts the ease and quickness, with which he can shake his hand at the wrist circularly (moving likewise, if he pleases, his arm at the elbow at the same time), in competition with the comparatively slow and laborious motion, with which his arm can be made to turn round at the shoulder, by the aid of a ball-and-socket joint.

III.—The *Spine*, or back-bone, is a chain of joints of very wonderful construction. Various, difficult, and almost inconsistent offices were to be executed by the same in-

strument. It was to be firm yet flexible (now I know no chain made by art which is both these; for by firmness I mean, not only strength, but stability); *firm*, to support the erect position of body; *flexible*, to allow of the bending of the trunk in all degrees of curvature. It was further also (which is another and quite a distinct purpose from the rest) to become a tube or conduit, for the safe conveyance from the brain of the most important substance of the animal frame, that, namely, upon which both sensation and motion depend, the *spinal marrow*; a substance not only of the first necessity to action, if not to life, but of a nature so delicate and tender, so susceptible, and so impatient<sup>t</sup> of injury, as that any unusual pressure upon it, or any considerable obstruction of its course, is followed by paralysis or death. Now the spine was not only to furnish the main canal for the passage of the medullary substance from the brain, but to give egress, in the course of its progress, to off-shoots therefrom, which, being afterwards indefinitely subdivided, might, under the name of nerves, distribute this exquisite supply to every part of the body. The same spine was also to serve another use not less wanted than the preceding, viz. to afford a fulcrum, stay, or basis (or, more properly speaking, a series of

these), for the insertion of the muscles which act upon this long lever or moveable column : and likewise to afford an attachment and to furnish a support for the ends of the ribs to rest upon.

Bespeak of a workman a piece of mechanism which shall comprise all these purposes, and let him set about to contrive it ; let him try his skill upon it ; let him feel the difficulty of accomplishing the task, before he be told how the same thing is effected in the animal frame. Nothing will enable him to judge so well of the wisdom which has been employed ; nothing will dispose him to think of it so truly.

The spine in man consists of twenty-four bones, which are so connected together by elastic cartilage or gristle, interposed between each two which are in juxtaposition, as to form a long, continuous lever, upon which numerous muscles act in bending the body in different directions. This column supports the head on its summit, and the accumulating weight of the arms and chest around it. Further, this column is perforated in its centre by a canal which lodges the spinal marrow. Thus it will be observed that the spine exemplifies all the offices required of bones in different parts of the skeleton ; and, in addition to these, it is requi-

site that the column should be pliable, whilst it retains its strength and secures the delicate nervous cord within it. To fulfil these purposes it is necessary that this long lever should be flexible; and this very property is its best security against injury from sudden and violent shocks, which would break, instead of simply bending, a continuous inflexible column. But it is also essential that its integral parts should be so knit together as to obviate the risk of dislocation from one another. This is accomplished by the firm adhesion of the intervening cartilage between the adjoining bones, and by the interlocking of the small joints between these bones; and so perfectly do these arrangements fulfil their office, that, although violence may break the bones, a simple displacement of one from another without such fracture can scarcely occur. Moreover, the mechanical arrangement of these connecting cartilages is peculiar and complicated, for they are disposed in concentric circles, which are very dense and resisting externally, but become gradually softer and more compressible within; whereby elastic yielding is combined with security. Furthermore, when the spine is viewed as a whole, it is observed that it becomes gradually thicker and stronger from above

downwards, and also that the interlocking of the bones with each other becomes successively closer ; and these conditions are obviously designed to compensate for the accumulating weight to be sustained, and the increasing leverage, and the consequently greater risk of fracture to which the column is subjected at its lower part. There is yet another and very interesting arrangement to be noticed, and that is the curves into which the spine is thrown, viz. a large backward curve in the centre, and a smaller one above and below, which are exactly equivalent to the single large curve. For what purpose do these exist ? In the first place, greater space is afforded for the lungs and heart in the chest; secondly, the column is much strengthened by the greater readiness with which these curves yield under pressure ; and thirdly, and perhaps most important of all, by this ready yielding the jar or shock which is conveyed upwards through the spine to the head, in running or jumping, is materially lessened. The spinal column is firmly fixed on the central bone of the pelvis or basin, and the superincumbent weight is thence distributed, through an irregular arch of bone on either side, to the lower extremities. The general result is, that not only the motions of the human body neces-

sary for the ordinary offices of life are performed with safety, but that it is an accident hardly ever heard of, that even the gesticulations of a harlequin injuriously distort his spine.

Upon the whole, and as a guide to those who may be inclined to carry the consideration of this subject further, there are three views under which the spine ought to be regarded, and in each of which it cannot fail to excite our admiration. These views relate to its articulations, its ligaments, and its perforation; and to the corresponding advantages which the body derives from these features of its construction, for action, for strength, and for that which is essential to every part, a secure communication with the brain.

In Fish, where great flexibility of the spine is required, for the purpose of permitting the lateral movements of the body in swimming, each vertebra is excavated into two conical cups, the apices of which are nearly or quite continuous. The hollow space which thus exists between each two contiguous vertebræ is occupied by a soft gelatinous substance, and the adjoining vertebræ are bound together by an elastic membrane, which permits of great freedom of movement, and aids in economizing muscular force.

In Serpents again, where similar flexibility is

essential, but greater strength and precision of movement are also indispensable, the construction of the spine is admirably adapted to

VERTEBRÆ OF COD, ETC.

1. Vertical section of two vertebræ of a Cod, showing their mode of connexion.

2. Two vertebræ of the Boa, seen from above.

fulfil the former requirement without sacrificing the latter; for each vertebra presents a smooth ball in front, which is fitted into a corresponding excavation or socket at the back part of the adjoining vertebra which is in front of it. Thus each two vertebræ which are in contact form a complete ball-and-socket joint between them, permitting free movement in every direction; which is, however, so far limited by lateral

joints, as to obviate the risk of displacement. Moreover, as snakes are dependent on the movements of their ribs for progression, these bones are united to the spine by joints, somewhat similar to those of the vertebræ with each other, and are moved by powerful muscles freely in every direction ;—far more freely than where the ribs merely form the walls of the chest, which rise and fall in breathing.

In Birds, the cervical vertebræ vary in number according to the length of the neck, which is adapted to the requirements of the animal ; and in this class the required flexibility is obtained by the different bones being joined together without the interposition of any elastic cartilage. But lower down, the vertebræ of the chest form a continuous chain of bones, firmly united together, to afford an unyielding support to the wings and the muscles which move them.

The structure and connexion of the bones of the Skull exemplify, in a remarkable way, mechanical contrivance. Its arched form renders it capable of resisting external violence ; and the texture of the bones which compose this vault is expressly designed to add to the strength of the whole. They consist of an outer layer which is tough and resisting like closely-fibred wood, and an inner layer which is

much more dense and brittle. Between these layers is an intervening space, occupied by a mesh-work of delicate bony fibres, which have the appearance of a series of cells. By this arrangement the effects of any jar or concussion are broken and diminished ; and the outer layer may be injured without the inner one necessarily suffering : and it may be added that each layer has its independent supply of blood from different sources ; so that if the outer layer perishes, the inner one may be preserved. The mode in which these two layers of bone are joined together in the arched segments of the skull is admirably adapted to their structure ; for the outer tough layer is united by the dove-tailing of the saw-like edges of the bones together, just as a cabinet-maker would work : but the inner layer of the adjoining bones, which is hard and fragile, is joined by simple adaptation of their margins, as the statuary would join two pieces of marble.

The Chest contains the heart and lungs, which are as important to life as the brain ; yet it is essential that its walls should admit of being altered in shape and capacity for the purposes of breathing. Its protection from injury is therefore secured in a different way from that which obtains in the skull, for its elasticity permits of its yielding to external

violence; and this property also economizes muscular power in breathing. The chief agency by which we draw in breath is an arched muscular partition between the chest and abdomen, which, by its contraction, encroaches upon the latter cavity; and thus the space in the chest is enlarged at its expense, and the air rushes in to fill the lungs. To facilitate these movements the ribs are joined to the spine by strong but moveable joints, and the space between each two adjoining ribs is occupied by muscles which draw them upwards and outwards; and the front ends of these bones are united to the breast-bone by elastic cartilage or gristle. In ordinary breathing the pressure of the elastic walls of the chest and lungs forces out the air; but when we cough or sneeze, the muscles of the abdomen compress that cavity and forcibly expel the air from the lungs.

The knee-pan or Patella is a nearly flat but thick bone, somewhat larger than a crown-piece, placed in front of the knee-joint, of which it forms a part. It answers two purposes; first, it is a protection to the joint, as in kneeling; and secondly, it gives considerable mechanical advantage to the great muscles which straighten the leg, for they are attached to the knee-pan

above, and this bone is again connected to the large bone of the leg by a strong ligament. Thus, in the hinge-like movements of the knee-joint, this little bone plays over the front of the lower end of the thigh-bone, as over a pulley. The convenience and advantage of this mechanism is obvious.

Throughout the skeleton, and especially in the limbs, the texture of the bones, in the arrangement of the fibres which compose them, is framed on the strictest mechanical principles, so as to add to their strength without increasing their weight.

#### OF THE JOINTS.

I. To almost all the bones belong *joints*; and in these, still more clearly than in the form or shape of the bones themselves, are seen both contrivance and contriving wisdom. Every joint is a curiosity, and is also strictly mechanical. There is the hinge-joint, and the ball-and-socket joint; each as manifestly such, and as accurately defined, as any which can be produced out of a cabinet-maker's shop: and one or the other prevails, as either is adapted to the motion which is wanted: e.g. a ball-and-socket joint is not required at the knee, the leg standing in need only of a motion backward and forward in

the same plane, for which a hinge-joint is sufficient; a ball-and-socket joint is wanted at the hip, that not only the progressive step may be provided for, but the interval between the limbs may be enlarged or contracted at pleasure. Now observe what would have been the inconvenience, i. e. both the superfluity and the defect of articulation, if the case had been inverted: if the ball-and-socket joint had been at the knee, and the hinge joint at the hip. The thighs must have been kept constantly together, and the legs have been loose and straddling. There would have been no use, that we know of, in being able to turn the calves of the legs before: and there would have been great confinement by restraining the motion of the thighs to one plane. The disadvantage would not have been less, if the joints at the hip and the knee had been both of the same sort; both balls and sockets, or both hinges: yet why, independently of utility, and of a Creator who consulted that utility, should the same bone (the thigh-bone) be rounded at one end, and channelled at the other?

II. Strong ligaments or bands extend over and around the ends of the bones, keeping the corresponding parts of the joint, i. e. the relative

convexities and concavities, in close application to each other.

For the *ball-and-socket joint* at the hip, beside the membrane already described, there is, as an additional security, a short, strong, yet flexible ligament, inserted by one end into the head of the ball, by the other into the cup; which ligament keeps the two parts of the joint so firmly in their place, that none of the motions which the limb naturally performs, none of the jerks and twists to which it is ordinarily liable, nothing less indeed than the utmost and the most unnatural violence, can pull them asunder. It is hardly imaginable, how great a force is necessary to break this ligament; yet it opposes no impediment to the suppleness of the joint. By its situation also, it is inaccessible to injury from sharp edges. As it can scarcely be ruptured (such is its strength), so it cannot be cut, except by an accident which would sever the limb. Moreover, there is a hollow at the bottom of the cup, in which this ligament is lodged, so that it may not interfere with the movements of the joint. If I had been permitted to frame a proof of contrivance, such as might satisfy the most distrustful inquirer, I know not whether I could have chosen an example of mechanism more

unequivocal, or more free from objection, than this ligament. Nothing can be more mechanical; nothing, however subservient to the safety, less capable of being generated by the action, of the joint. I would particularly solicit the reader's attention to this provision, as it is found in the head of the *thigh-bone*; to its strength, its structure, and its use. It is an instance upon which I lay my hand. One single fact, weighed by a mind in earnest, leaves oftentimes the deepest impression. For the purpose of addressing different understandings and different apprehensions,—for the purpose of sentiment, for the purpose of exciting admiration of the Creator's works, we diversify our views, we multiply examples; but for the purpose of strict argument, one clear instance is sufficient: and not only sufficient, but capable perhaps of generating a firmer assurance than what can arise from a divided attention.

The ends of bones forming the hinge-joints are also usually tied together by outside ligaments only; but the knee presents a remarkable exception to this rule. In order to facilitate free movement in this large joint, the cup on the great bone of the leg, the tibia, is shallow; and although the outside ligaments are strong, the interior of the joint has two very thick

bands, which cross each other as they pass from the thigh-bone to the tibia. Their special use, besides the general strength they afford, is to limit the twisting or rotatory movement of one bone on the other. Moreover the cups on the head of the tibia—for the hollow on this bone is divided in the centre—are deepened by two crescentic cartilages interposed between the joint-surfaces. Freedom of movement is thus increased, whilst risk of displacement is diminished.

ARCH OF THE HUMAN FOOT.

Bones of the human foot, showing its arched form, and the part articulating with the bones of the leg to form the ankle-joint.

Another no less important joint is the *ankle*; yet though important it is (in order, perhaps, to preserve the symmetry and lightness of the limb) *small*, and, on that account, more liable to injury. Now this joint is strengthened, i. e. is defended from dislocation, by two remarkable processes or prolongations of the bones of the leg: which processes form the protuberances that we call the inner and outer ankle. These are formed by a part of each bone going down

lower than the other part, and thereby overlapping the joint; so that, if the joint be in danger of slipping outward, it is curbed by the inner projection, i. e. that of the tibia; if inward, by the outer projection, i. e. that of the fibula. Between both, it is locked in its position. I know no account that can be given of this structure, except its utility. Why should the tibia terminate, at its lower extremity, with a double end, and the fibula the same—but to barricade the joint on both sides by a continuation of part of the thickness of the bone over it?

III. The joint at the *shoulder* compared with the joint at the *hip*, though both are ball-and-socket joints, discovers a difference in their form and proportions, well suited to the different offices which the limbs have to execute. The cup or socket at the shoulder is much shallower and flatter than it is at the hip, and is also in part formed of cartilage set round the rim of the cup. The socket, into which the head of the thigh-bone is inserted, is deeper, and made of more solid materials. This agrees with the duties assigned to each part. The arm is an instrument of motion, principally, if not solely. Accordingly the shallowness of the socket at the shoulder, and the large size of the ball which plays in it, are excellently adapted for the allowance of a

free motion and a wide range, both of which the arm wants; and the strong tendons which enclose the joint compensate for its natural weakness of form. Whereas, in the case of the lower limb, forming a part of the column of the body, having to support the body, as well as to be the means of its locomotion, firmness was to be consulted, as well as action. With a capacity for motion, in all directions indeed, as at the shoulder, but not in any direction to the same extent as in the arm, was to be united stability, or resistance to dislocation.

The suppleness and pliability of the joints we every moment experience; and the *firmness* of animal articulation, the property we have hitherto been considering, may be judged of from this single observation, that, at any given moment of time, there are millions of animal joints in complete repair and use, for one that is dislocated; and this, notwithstanding the contortions and wrenches to which the limbs of animals are continually subject.

IV. In all joints that are moveable, the ends of the bones are covered with cartilage or gristle, which, from its smooth and elastic nature, contributes greatly to the ease with which they work against each other, and also to diminish the effect of jarring of the surfaces from vio-

lence. The minute arrangement of this cartilage structure, where subject to pressure and friction, resembles that of the pile on the surface of velvet.

In some joints, very particularly in the knees, there are loose cartilages or gristles between the bones, and within the joint, so that the ends of the bones, instead of working upon one another, work upon the intermediate cartilages. Thus, these joints are deepened, and they work more freely, with less risk of displacement.

V. We have now done with the configuration ; but there is also in the joints, and that common to them all, another exquisite provision, manifestly adapted to their use, and concerning which there can, I think, be no dispute ; namely, the regular supply of a *mucilage*, more emollient and slippery than oil itself, which is constantly softening and lubricating the parts that rub upon each other, and thereby diminishing the effect of attrition in the highest possible degree. The manner in which grease is supplied from a box to the axle of a rapidly revolving wheel may be said, in some sort, to represent the contrivance in the animal joint ; with this superiority, however, on the part of the joint, viz. that here, the oil is not only dropped, but *made*.

In considering the joints, there is nothing, perhaps, which ought to move our gratitude more than the reflection, *how well they wear*. A limb shall swing upon its hinge, or play in its socket, many hundred times in an hour, for sixty years together, without diminution of its agility: which is a long time for anything to last; for anything so much worked and exercised as the joints are. This durability I should attribute, in part, to the provision which is made for the preventing of wear and tear, first, by the polish of the cartilaginous surfaces; secondly, by the lubrication of the mucilage; and, in part, to that astonishing property of animal constitutions, assimilation, by which, in every portion of the body, let it consist\* of what it will, substance is restored, and waste repaired.

Moveable joints, I think, compose the curiosity of bones; but their union, even where no motion is intended or wanted, carries marks of mechanism and of mechanical wisdom. The teeth, especially the front teeth, are one bone fixed in another, like a peg driven into a board. The sutures of the skull are like the edges of two saws clapped together, in such a manner as that the teeth of one enter the intervals of the other. We have sometimes one bone lapping

over another, and planed down at the edges; sometimes also the thin lamella of one bone received into a narrow furrow of another. In all which varieties we seem to discover the same design, viz. firmness of juncture, without clumsiness in the seam.

## CHAPTER IX.

## OF THE MUSCLES.

MUSCLES, with their tendons, are the instruments by which animal motion is performed. It will be our business to point out instances in which, and properties with respect to which, the disposition of these muscles is as strictly mechanical, as that of the wires and strings of a puppet.

I. We may observe, what I believe is universal, an exact relation between the joint and the muscles which move it. Whatever motion the joint, by its mechanical construction, is capable of performing, that motion the annexed muscles, by their position, are capable of producing. For example; if there be, as at the knee and elbow, a hinge-joint, capable of motion only in the same plane, the leaders as they are called, i. e. the muscular tendons, are placed in directions parallel to the bone, so as, by the contraction

or relaxation of the muscles to which they belong, to produce that motion and no other. If these joints were capable of a freer motion, there are no muscles to produce it. Whereas at the shoulder and the hip, where the ball and socket joint allows by its construction of a rotatory or sweeping motion, tendons are placed in such a position, and pull in such a direction, as to produce the motion of which the joint admits. For instance, the *sartorius* or tailor's muscle, rising from the pelvis, running diagonally across the thigh, and taking hold of the inside of the main bone of the leg, a little below the knee, enables us, by its contraction, to throw one leg over the other, and to roll the thigh outwards, giving effect, at the same time, to the ball-and-socket joint at the hip, and the hinge joint at the knee. There is, as we have seen, a specific mechanism in the bones, for the rotatory motions of the head and hands: there is, also, in the oblique direction of the muscles belonging to them, a specific provision for the putting of this mechanism of the bones into action. And mark the consent of uses. The oblique muscles would have been inefficient without that particular articulation; that particular articulation would have been lost, without the oblique muscles. It may be proper,

however, to observe with respect to the *head*, although I think it does not vary the case, that its oblique motions and inclinations are often motions in a *diagonal*, produced by the joint action of muscles lying in straight directions. But whether the pull be single or combined, the articulation is always such, as to be capable of obeying the action of the muscles. The oblique muscles attached to the head are likewise so disposed, as to be capable of steadyng as well as of moving it. The head of a new-born infant is often obliged to be filleted up. After death, the head drops and rolls in every direction. So that it is by the *equilibre* of the muscles, by the aid of a considerable and equipollent muscular force in constant exertion, that the head maintains its erect posture. The muscles here supply what would otherwise be a great defect in the articulation; for the joint in the neck, although admirably adapted to the motion of the head, is insufficient for its support. It is not only by the means of a most curious structure of the bones that a man turns his head, but by virtue of an adjusted muscular power, that he even holds it up.

As another example of what we are illustrating, viz. conformity of use between the bones and the muscles, the surface of the joint is exactly

proportioned to the quantity of motion which the respective muscles are capable of producing.

The action of most muscles is controlled by the will; and for that purpose it is, of course, necessary that the existing condition of the muscle, as to its preparedness to act, should be perceived and known, otherwise volition could not be exercised. We can be made acquainted with this only by nerves communicating between the muscle and the brain, from which the mandate of the will is issued. It has been proposed to call this perception the *muscular sense*.

II. A muscle acts only by contraction. Its force is exerted in no other way. When the exertion ceases, it relaxes itself, that is, it returns by simple relaxation to its former state. This is the nature of the muscular fibre; and being so, it is evident that the reciprocal energetic motion of the limbs, by which we mean motion *with force* in opposite directions, can only be produced by the instrumentality of opposite or antagonist muscles; of flexors and extensors answering to each other. For instance, the biceps and brachiaetus anticus muscles, placed in the front part of the upper arm, by their contraction bend the elbow; and with such degree of force as the case requires, or the strength admits of. The relaxation of these muscles,

Fig. 1

Fig. 2

Fig. 1. Muscles (flexors) for bending the arm: A the *biceps* originating at two points, B, on the scapula, and attached by a tendon to the radius C; also the inner muscle, *brachialis anticus*, D, inserted at E, on the ulna.

Fig. 2. The muscle for extending the arm, the *triceps*, A, the three portions of which, B, arise from the humerus, D, and scapula E, being inserted at the olecranon process, or elbow, C; this muscle is also shown in Fig 1, attached to the elbow at F.

after the effort, would merely let the fore-arm drop down. For the *back stroke*, therefore, and that the arm may not only bend at the elbow, but also extend and straighten itself with force, other muscles, the triceps and the anconæus, placed on the hinder part of the arms, by their contractile twitch fetch back the fore-arm into a straight line with the cubit, with no less force than that with which it was bent out of it. The same thing obtains in all the limbs, and in every moveable part of the body. A finger is not bent and straightened, without the *contraction* of two muscles taking place. It is evident, therefore, that the animal functions require that particular disposition of the muscles which we describe by the name of antagonist muscles. And they are accordingly so disposed. They act, like two sawyers in a pit, by an opposite pull: and nothing surely can more strongly indicate design and attention to an end, than their being thus stationed, than this collocation. The nature of the muscular fibre being what it is, the purposes of the animal could be answered by no other. And not only the capacity for motion, but the aspect and symmetry of the body, is preserved by the muscles being marshalled according to this order; e. g. the mouth is holden in the middle of the face, and its

angles kept in a state of exact correspondence, by two muscles drawing against and balancing

MUSCLES OF THE FACE,

To show the sphincter of the mouth and eye. One side exhibits the superficial muscles, and the other those which lie immediately beneath them.

each other. In a hemiplegia, when the muscle on one side is weakened, the muscle on the other side draws the mouth awry.

III. Another property of the muscles, which could only be the result of care, is, their being almost universally so disposed, as not to obstruct or interfere with one another's action. Now, when we reflect upon the number of muscles, between four and five hundred, in the human body, known and named; how contiguous they lie to each other, in layers, as it were, over one another, crossing one another, sometimes embedded in one another, sometimes perforating one another: we cannot but be convinced that an arrangement, which leaves to each its liberty and its full play, must necessarily have required meditation and counsel.

IV. The following is oftentimes the case with the muscles. Their action is wanted where their situation would be inconvenient. In which case, the body of the muscle is placed in some commodious position at a distance, and made to communicate with the point of action, by slender strings or wires. If the muscles which move the fingers had been placed in the palm or back of the hand, they would have swelled that part to an awkward and clumsy thickness. The beauty, the proportions, and the utility of the part, would have been destroyed. They are therefore disposed in the arm, and even up to the elbow; and act by long tendons, strapped

down at the wrist, and passing under the ligaments to the fingers, and to the joints of the fingers, which they are severally to move. In like manner, the muscles which move the toes, and many of the joints of the foot, how gracefully are they disposed in the calf of the leg, instead of forming an unwieldy tumefaction in the foot itself! The observation may be repeated of the muscle which draws the nictitating membrane over the eye. Its office is in the front of the eye; but its body is lodged in the back part of the globe, where it lies safe, and where it encumbers nothing.

V. The great mechanical variety in the figure of the muscles may be thus stated. It appears to be a fixed law, that the contraction of a muscle shall be towards its centre. Therefore the subject for mechanism on each occasion is, so to modify the figure, and adjust the position of the muscle, as to produce the motion required, agreeably with this law. This can only be done by giving to different muscles a diversity of configuration, suited to their several offices, and to their situation with respect to the work which they have to perform. On which account we find them under a multiplicity of forms and attitudes; sometimes with double, sometimes with treble, tendons, sometimes with

---

none: sometimes one tendon to several muscles, at other times one muscle to several tendons. Again, the obliquity in the course of the fibres of a muscle, as they pass to be inserted into its tendon, adds velocity to their movement, though with a corresponding sacrifice of power. The shape of the organ is susceptible of an incalculable variety, whilst the original property of the muscle, the law and line of its contraction, remains the same, and is simple. Herein the muscular system may be said to bear a perfect resemblance to our works of art. An artist does not alter the native quality of his materials, or their laws of action. He takes these as he finds them. His skill and ingenuity are employed in turning them, such as they are, to his account, by giving to the parts of his machine a form and relation, in which these unalterable properties may operate to the production of the effects intended.

VI. The ejaculations can never too often be repeated;—How many things must go right for us to be an hour at ease! how many more for us to be vigorous and active! Yet vigour and activity are, in a vast plurality of instances, preserved in human bodies, notwithstanding that they depend upon so great a number of instruments of motion, and notwithstanding

that the defect or disorder sometimes of a very small instrument, of a single pair, for instance, out of the four hundred and fifty muscles which are employed, may be attended with grievous inconveniency. There is piety and good sense in the following observation, taken out of the *Religious Philosopher*: “With much compassion,” says this writer, “as well as astonishment at the goodness of our loving Creator, have I considered the sad state of a certain gentleman, who, as to the rest, was in pretty good health, but only wanted the use of these *two little muscles* that serve to lift up the eyelids, and so had almost lost the use of his sight, being forced, as long as this defect lasted, to shove up his eyelids every moment with his own hands!”—In general we may remark in how small a degree those, who enjoy the perfect use of their organs, know the comprehensiveness of the blessing, the variety of their obligation. They perceive a result, but they think little of the multitude of concurrences and rectitudes which go to form it.

Beside these observations, which belong to the muscular organ as such, we may notice some advantages of structure, which are more conspicuous in muscles of a certain class or description than in others. Thus:—

I. The variety, quickness, and precision, of which muscular motion is capable, are seen, I think, in no part so remarkably as in the *tongue*. It is worth any man's while to watch the agility of his tongue; the wonderful promptitude with which it executes changes of position, and the perfect exactness. Each syllable of articulated sound requires for its utterance a specific action of the tongue, and of the parts adjacent to it. The disposition and configuration of the mouth, appertaining to every letter and word, is not only peculiar, but, if nicely and accurately attended to, perceptible to the sight; insomuch, that curious persons have availed themselves of this circumstance to teach the deaf to speak, and to understand what is said by others. In the same person, and after his habit of speaking is formed, one, and only one, position of the parts, will produce a given articulate sound correctly. How instantaneously are these positions assumed and dismissed! how numerous are the permutations, how various, yet how infallible! Arbitrary and antic variety is not the thing we admire; but variety obeying a rule, conduced to an effect, and commensurate with exigencies infinitely diversified. I believe also that the anatomy of the tongue corresponds with these observations upon its activity. The muscles of

the tongue are numerous, and implicated with one another; nevertheless (which is a great perfection of the organ), neither the number nor the complexity in any wise impede its motion, or render the determination or success of its efforts uncertain.

I HERE entreat the reader's permission, to step a little out of my way to consider *the parts of the mouth*, in some of their other properties. It has been said that, whenever nature attempts to work two or more purposes by one instrument, she does both or all imperfectly. Is this true of the tongue, regarded as an instrument of speech, and of taste; or regarded as an instrument of speech, of taste, and of deglutition? So much otherwise, that many persons, that is to say, nine hundred and ninety-nine persons out of a thousand, by the instrumentality of this one organ, talk, and taste, and swallow, very well. In fact, the constant warmth and moisture of the tongue, the thinness of the skin, the papillæ upon its surface, qualify this organ for its office of tasting, as much as its multiplicity of fibres do for the rapid movements which are necessary to speech. Animals which feed upon grass have their tongues covered with a perforated skin, so as to admit the dissolved

---

food to the papillæ underneath, which, in the meantime, remain defended from the rough action of the unbruised spiculæ.

There are brought together within the cavity of the mouth more distinct uses, and parts executing more distinct offices, than I think can be found lying so near to one another, or within the same compass, in any other portion of the body ; viz. teeth of different shape, first for cutting, secondly for grinding ; muscles, most artificially disposed for carrying on the compound motion of the lower jaw, half lateral and half vertical, by which the mill is worked : fountains of saliva, springing up in different parts of the cavity for the moistening of the food, whilst the mastication is going on : glands, to feed the fountains ; a muscular constriction of a very peculiar kind in the back part of the cavity, for the guiding of the prepared aliment into its passage towards the stomach, and in many cases for carrying it along that passage ; for, although we may imagine this to be done simply by the weight of the food itself, it in truth is not so, even in the upright posture of the human neck ; and most evidently is not the case with quadrupeds, with a horse for instance, in which, when pasturing, the food is thrust upward by muscular strength, instead of descending of its own accord.

In the meantime, and within the same cavity, is going on another business, altogether different from what is here described,—that of respiration and speech. In addition therefore to all that has been mentioned, we have a passage opened, from this cavity to the lungs, for the admission of air, exclusively of every other substance ; we have muscles, some in the larynx, and without number in the tongue, for the purpose of modulating that air in its passage, with a variety, a compass and precision, of which no other musical instrument is capable. And lastly, which in my opinion crowns the whole as a piece of machinery, we have a specific contrivance for dividing the pneumatic part from the mechanical, and for preventing one set of actions interfering with the other. Where various functions are united, the difficulty is to guard against the inconveniences of a too great complexity. In no apparatus put together by art, and for the purposes of art, do I know such multifarious uses so aptly combined, as in the natural organization of the human mouth ; or, where the structure, compared with the uses, is so simple. The mouth, with all these intentions to serve, is a single cavity ; is one machine ; with its parts neither crowded nor confused, and each unembarrassed by the rest : each at least at liberty in a degree sufficient for

the end to be attained. If we cannot eat and sing at the same moment, we can eat one moment, and sing the next: the respiration proceeding freely all the while.

There is one case however of this double office, and that of the *earliest* necessity, which the mouth alone could not perform; and that is, carrying on together the two actions of sucking and breathing. Another route therefore is opened for the air, namely, through the nose, which lets the breath pass backward and forward, whilst the lips, in the act of sucking, are necessarily shut close upon the body from which the nutriment is drawn. This is a circumstance which always appeared to me worthy of notice. The nose would have been necessary, although it had not been the organ of smelling. The making it the seat of a sense, was superadding a new use to a part already wanted; was taking a wise advantage of an antecedent and a constitutional necessity.

BUT to return to that which is the proper subject of the present section,—the celerity and precision of muscular motion. These qualities may be particularly observed in the execution of many species of instrumental *music*, in which the changes produced by the hand of the musician

are exceedingly rapid ; are exactly measured, even when most minute ; and display, on the part of the muscles, an obedience of action, alike wonderful for its quickness and its correctness.

Or let a person only observe his own hand whilst he is *writing* ; the number of muscles which are brought to bear upon the pen ; how the joint and adjusted operation of several muscles is concerned in every stroke, yet that five hundred such strokes are drawn in a minute. Not a letter can be turned without more than one, or two, or three muscular contractions, definite, both as to the choice of the muscle, and as to the space through which the contraction moves ; yet how currently does the work proceed ! and when we look at it, how faithful have the muscles been to their duty, how true to the order which endeavour or habit hath inculcated ! For let it be remembered that, whilst a man's hand-writing is the same, an exactitude of order is preserved, whether he write well, or ill. These two instances, of music and writing, show not only the quickness and precision of muscular action, but the docility.

II. Regarding the particular configuration of muscles, *sphincter* or circular muscles appear to me admirable pieces of mechanism. It is the muscular power most happily applied : the same

quality of the muscular substance, but under a new modification. The circular disposition of the fibres is strictly mechanical; but, though the most mechanical, is not the only thing in sphincters which deserves our notice. The regulated degree of contractile force with which they are endowed, sufficient for retention, yet vincible when requisite, together with their ordinary state of actual contraction, by means of which their dependence upon the will is not constant, but occasional, gives to them a constitution, of which the conveniency is inestimable. This, their semi-voluntary character, is exactly such as suits with the wants and functions of the animal.

III. We may also, while upon the subject of muscles, observe, that many of our most important actions are achieved by the combined help of different muscles. Frequently a diagonal motion is produced, by the contraction of tendons pulling in the direction of the sides of the parallelogram. This is the case, as hath been already noticed, with some of the oblique nutations of the head. Sometimes the number of co-operating muscles is very great. Such is the case every time we breathe; yet we take in, or let out, our breath, without reflecting what a work is thereby performed: what an apparatus

is laid in of instruments for the service, and how many such contribute their assistance to the effect! Breathing with ease is a blessing of every moment; yet, of all others, it is that which we possess with the least consciousness. A man in an asthma is the only man who knows how to estimate it.

IV. Some of the most important and the most delicate actions are performed in the body by the smallest muscles; as, for instance, around the pupil of the eye, and in the drum of the ear. The tenuity of these muscles is astonishing; yet are they real, effective muscles; and not only such, but the grandest and most precious of our faculties, sight and hearing, depend upon their health and action.

V. The muscles act in the limbs with what is called a mechanical disadvantage. The muscle at the shoulder, by which the arm is raised, is fixed nearly in the same manner as the load is fixed upon a steelyard, within a few decimals, we will say, of an inch, from the centre upon which the steelyard turns. In this situation, we find that a very heavy draught is no more than sufficient to countervail the force of a small lead plummet, placed upon the long arm of the steelyard, at the distance of perhaps fifteen or twenty inches from the centre, and on the other side of it.

And this is the disadvantage which is meant. And an absolute disadvantage, no doubt, it would be, if the object were to spare the force of muscular contraction. But observe how conducive is this constitution to animal conveniency. Mechanism has always in view one or other of these two purposes; either to move a great weight slowly, and through a small space, or to move a light weight rapidly, through a considerable sweep. For the former of these purposes, a different species of lever, and a different collocation of the muscles, might be better than the present; but for the second, the present structure is the true one. Now so it happens, that the second, and not the first, is that which the occasions of animal life principally call for. In what concerns the human body, it is of much more consequence to any man to be able to carry his hand to his head with due expedition, than it would be to have the power of raising from the ground a heavier load (of two or three more hundredweight, we will suppose,) than he can lift at present. This last is a faculty which, on some extraordinary occasions, he may desire to possess; but the other is what he wants and uses every hour or minute. In like manner, a husbandman, or a gardener, will do more execution, by being

able to carry his scythe, his rake, or his flail, with a sufficient despatch through a sufficient space, than if, with greater strength, his motions were proportionably more confined and slow. It is the same with a mechanic in the use of his tools. It is the same also with other animals in the use of their limbs. In general, the vivacity of their motions would be ill exchanged for greater force under a clumsier structure.

We have offered our observations upon the structure of muscles in general; we have also noticed certain species of muscles: but there are also *single* muscles, which bear marks of mechanical contrivance appropriate as well as particular. Out of many instances of this kind, we select the following.

I. Of muscular actions, even of those which are well understood, some of the most curious are incapable of popular explanation; at least, without the aid of plates and figures. This is in a great measure the case with a very familiar, but, at the same time, a very complicated motion,—that of the *lower jaw*; and with the muscular structure by which it is produced. One of the muscles concerned may, however, be described in such a manner, as to be, I think, sufficiently comprehended for our present pur-

pose. The problem is to pull the lower jaw *down*. The obvious method should seem to be, to place a straight muscle, viz. to fix a string from the chin to the breast, the contraction of which would open the mouth, and produce the motion required at once. But it is evident that the form and liberty of the neck forbid a muscle being laid in such a position; and that, consistently with the preservation of this form, the motion, which we want, must be effectuated by some muscular mechanism disposed further back in the jaw. The mechanism adopted is as follows. A certain muscle called the *diagastric*, rises on the side of the neck, somewhat behind the insertion of the lower jaw, and comes down, being converted in its progress into a round tendon. Now, it is manifest that the tendon, whilst it pursues a direction *descending* towards the jaw, must, by its contraction, pull the jaw up, instead of down. What then was to be done? This, we find, is done. The descending tendon, when it is got low enough, is passed through a loop, or ring, or pulley, in the *os hyoïdes*, and then made to ascend; and, having thus changed its line of direction, is inserted into the inner part of the chin: by which device, viz. the turn at the loop, the action of the muscle (which in all muscles is contraction) that before would

have pulled the jaw up, now as necessarily draws it down.

II. What contrivance can be more mechanical than the following, viz. a slit in one tendon to let another tendon pass through it? This structure is found in the tendons which move the toes and fingers. The long tendon, as it is called, in the foot which bends the first joint of the toe, passes *through* the short tendon which bends the second joint; which course allows to the sinew more liberty, and a more commodious action than it would otherwise have been capable of exerting. There is nothing, I believe, in a silk or cotton mill, in the belts, or straps, or ropes, by which motion is communicated from one part of the machine to another, that is more artificial, or more evidently so, than this *perforation*.

III. The next circumstance which I shall mention, under this head of muscular arrangement, is so decisive a mark of intention, that it always appeared to me to supersede, in some measure, the necessity of seeking for any other observation upon the subject: and that circumstance is, the tendons which pass from the leg to the foot, being bound down by a ligament at the ankle. The foot is placed at a considerable angle with the leg. It is manifest, therefore,

that flexible strings passing along the interior of the angle, if left to themselves, would, when stretched, start from it. The obvious preventive is to tie them down. And this is done in fact. Across the instep, or rather just above it, the anatomist finds a strong ligament, *under* which the tendons pass to the foot. The effect of the ligament, as a bandage, can be made evident to the senses: for if it be cut, the tendons start up. The simplicity, yet the clearness of this contrivance, its exact resemblance to established resources of art, place it amongst the most indubitable manifestations of design with which we are acquainted.

I have sometimes wondered, why we are not struck with mechanism in animal bodies, as readily and as strongly as we are struck with it, at first sight, in a watch or a mill. One reason of the difference may be, that animal bodies are, in a great measure, made up of soft, flabby substances, such as muscles and membranes; whereas we have been accustomed to trace mechanism in sharp lines, in the configuration of hard materials, in the moulding, chiseling, and filing into shapes, of such articles as metals or wood. There is something therefore of habit in the case; but it is sufficiently evident, that there can be no proper reason for

any distinction of the sort. Mechanism may be displayed in the one kind of substance, as well as in the other.

Although the few instances we have selected, even as they stand in our description, are nothing short perhaps of logical proofs of design, yet it must not be forgotten that, in every part of anatomy, description is a poor substitute for inspection. It is well said by an able anatomist,<sup>1</sup> and said in reference to the very part of the subject which we have been treating of;—“*Imperfecta hæc muscularum descriptio, non minùs arida est legentibus, quàm inspectantibus fuerit jucunda eorundem præparatio. Elegantissima enim mechanicē artificia, creberrimè in illis obvia, verbis nonnisi obscurè exprimuntur: carnum autem ductu, tendinum colore, insertionum proportione, et trochlearum distributione, oculis exposita, omnem superant admirationem.*”

<sup>1</sup> Steno, in *Blas. Anat. Animal.* p. 2, c. 4.

## CHAPTER X.

### OF THE VESSELS OF ANIMAL BODIES.

THE circulation of the *blood* through the bodies of men and quadrupeds, and the apparatus by which it is carried on, compose a system, and testify a contrivance, as well understood as any part of the animal frame. The lymphatic system, or the nervous system, may be more subtile and intricate; nay, it is possible that in their structure they may be even more artificial than the sanguiferous; but we do not know so much about them.

The utility of the circulation of the blood, I assume as an acknowledged point. One grand purpose is plainly answered by it; the distributing to every part, every extremity, every nook and corner of the body, the nourishment which is received into it by one aperture. What enters at the mouth finds its way to the fingers' ends. A more difficult mechanical problem could

---

hardly I think be proposed, than to discover a method of constantly repairing the waste, and of supplying an accession of substance to every part of a complicated machine, at the same time.

This system presents itself under two views : first, the disposition of the blood-vessels, i. e. the laying of the pipes; and, secondly, the construction of the engine at the centre, viz. the heart, for driving the blood through them.

I. The disposition of the blood-vessels, as far as regards the supply of the body, is like that of the water-pipes in a city, viz. large and main trunks branching off by smaller pipes (and these again by still narrower tubes) in every direction, and towards every part in which the fluid, which they convey, can be wanted. So far the water-pipes, which serve a town, may represent the vessels which carry the blood from the heart. But there is another thing necessary to the blood, which is not wanted for the water ; and that is, the carrying of it back again to its source. For this office, a reversed system of vessels is prepared, which, uniting at their extremities with the extremities of the first system, collects the divided and subdivided streamlets, first, by capillary ramifications into larger branches ; secondly, by these branches into trunks ; and thus returns the blood (almost

exactly inverting the order in which it went out) to the fountain whence its motion proceeded. All which is evident mechanism.

## PLAN OF CIRCULATION.

Plan of the circulation of the blood through the heart and lungs, and the body generally.

The body, therefore, contains two systems of blood-vessels, arteries and veins. Between the constitutions of the systems there are also certain differences, suited to the functions which

the systems have to execute. As it is requisite that the blood should be propelled with more force through the arteries or conveying vessels, their structure is adapted to facilitate this result; they are much thicker than the veins, and contain a large quantity of elastic tissue, so that after being distended by the heart's action they contract of themselves, and thus help the blood onward in its course. But at a distance from the heart, where the force of its contraction is but little felt in the arteries, there is a proportionate diminution in the elastic properties of these vessels, in place of which muscularity is substituted; so that their elasticity and muscularity exist in an inverse proportion in relation to their distance from the heart. In other words, where elasticity would be valueless, and where the impulse produced by the contraction of the heart itself cannot reach, there the small arteries are endowed with a muscular coat, to help the passage of the blood through them; and as this muscular coat is supplied by a special set of nerves, the quantity of blood passing through these small vessels is regulated by this muscular coat, according to the requirements of the part supplied.

The position of the larger arteries, as they proceed to their destination, is the best that could be arranged for their security from

injury; as on the inside of the limbs, imbedded among muscles, protected by bone, &c.

The veins, or conduits by which the blood is returned to the heart, are much thinner, and are comparatively passive or inert in the transmission of this fluid; but they possess a very interesting and remarkable contrivance, which is purely mechanical, and essential to the due

VALVES OF VEINS.

performance of their function. As their delicate structure is subjected to pressure by contraction of the muscles in their neighbourhood, the blood would be driven in every direction, backwards as well as forwards, were these vessels not provided with valves at intervals, by which the retrograde course of the blood is prevented. Moreover, the veins run much more on the

surface, immediately beneath the skin, and their communications with each other by cross branches are more frequent than in the arteries.

II. The next thing to be considered is the

THE HEART AND LUNGS.

*a*, the heart; *b*, the great pulmonary artery carrying the blood into the lungs; *c c c*, the lungs, spread out and pinned in their positions; *d d d d*, the pulmonary veins bringing the blood from the lungs to the heart; *e*, the trachea.

engine which works this machinery, viz. the *heart*. For our purpose it is unnecessary to ascertain the principle upon which the heart acts. Whether it be irritation excited by the

contact of the blood, by the influx of the nervous fluid, or whatever else be the cause of its motion, it is something which is capable of producing, in a living, muscular fibre, alternate contraction and relaxation. This is the power we have to work with; and the inquiry is, how this power is applied in the instance before us. There is provided, in the central part of the body, a hollow muscle, composed of intricately-arranged spiral fibres; in some animals, however, appearing to be semi-circular rather than spiral. By the contraction of these fibres, the sides of the muscular cavities are necessarily squeezed together, so as to force out from them any fluid which they may at that time contain; by the relaxation of the same fibres, the cavities are in their turn dilated, and, of course, prepared to admit every fluid which may be poured into them. Into these cavities are inserted the great trunks, both of the arteries which carry out the blood, and of the veins which bring it back. This is a general account of the apparatus; and the simplest idea of its action is, that, by each contraction a portion of blood is forced by a syringe into the arteries: and, at each dilatation, an equal portion is received from the veins. This produces, at each pulse, a motion and change in the mass of blood, to the amount of

what the cavity contains, which in a full-grown human heart, I understand, is about an ounce, or two table-spoons full. How quickly these changes succeed one another, and by this succession how sufficient they are to support a stream or circulation throughout the system, may be understood by the following computation :—

It is calculated that the quantity of blood in the body of an adult is from fifteen to twenty pounds, and that the circulation of the whole mass is completed in less than two minutes. The mind is filled with wonder when we contemplate this marvellous and unceasing activity ; unceasing, that is, in the sense that it is unremitting ; yet is this rhythmic action broken by the equally constant and necessary period of repose : the auricles and ventricles contract in rapid succession, and then there is an interval of rest and preparation for the succeeding stroke : just as, in breathing, we draw in the air, and after its expulsion from the lungs there is a pause of repose.

The account which we have here given, of the injection of blood into the arteries by the contraction, and of the corresponding reception of it from the veins by the dilatation, of the cavities of the heart, and of the circulation being

thereby maintained through the blood-vessels of the body, is true, but imperfect. The heart performs this office, but it is in conjunction with another of equal curiosity and importance. It is necessary that the blood should be successively brought into contact, or contiguity, or proximity, with the *air*.

The reason of this necessity is that the blood, in the performance of its office during its circulation, is constantly accumulating an impurity —the result, so to speak, of animal combustion—which it is requisite to remove: and as this impurity, carbon, cannot be thrown off in a solid form, it requires to be combined with oxygen gas, so as to form another gas called carbonic acid. Now, the atmospheric air contains this needed oxygen, combined with another gas, nitrogen, in the proportion of one part of the former to four of the latter. In breathing it is found that the oxygen is the ingredient which is taken into the blood, the nitrogen being present simply to dilute it. Let us now observe the admirable arrangement by which this essential exposure of the blood to the air is accomplished.

By the bellows-like action of the chest, already described, the atmospheric air is drawn into the lungs, passing along the great air-tube called the trachea, and thence through its rami-

fications, which divide and subdivide like the branches of a tree, and finally terminate in millions of little bags, called air-cells. Suppose the stalk of a bunch of grapes to be larger, and perforated so as to form a tube branching off to every grape, and the skins of the grapes to be empty, this would serve as a coarse illustration of what is meant; and each time air is drawn into this tube, the grape-skins would be distended. Next, respecting the mode in which the blood gets to these air-cells. The heart, which is devoted to the circulation of the blood through the *body*, has its counterpart in a separate heart which is devoted to the circulation through the *lungs*; but both hearts are bound up together so as to form but one mass in the higher animals; yet the two sides are distinct. The impure blood, charged with carbonic acid gas, is received by the right auricle, and conveyed from it into the right ventricle, whence it is propelled through a large artery, which divides and distributes it to the lungs. These arteries divide and subdivide, in company with the divisions of the air-tubes, until finally they terminate in numberless hair-like tubes called *capillaries*, on the surface of the air-cells, the delicate texture of which admits of the free interchange of gases, the

carbonic acid being given off, and oxygen imbibed.

Thus, it will be understood that, for the complete circulation of the blood, four cavities in the heart are necessary; and four are accordingly provided: two, called ventricles, which *send out* the blood, viz. one into the lungs, in the first instance; the other into the mass of the body, after it has returned from the lungs: two others also, called auricles, which *receive* the blood from the veins; viz. one, as it comes immediately from the body; the other, as the same blood comes a second time after its circulation through the lungs. So that there are two receiving cavities, and two forcing cavities. The structure of the heart has reference to the lungs; for without the lungs one of each would have been sufficient. The translation of the blood in the heart itself is after this manner. The receiving cavities respectively communicate with the forcing cavities, and, by their contraction, unload the received blood into them. The forcing cavities, when it is their turn to contract, compel the same blood into the mouths of the arteries.

The account here given will not convey to a reader, ignorant of anatomy, anything like an

accurate notion of the form, action, or use of the parts (nor can any short and popular account do this); but it is abundantly sufficient to testify contrivance; and although imperfect, being true as far as it goes, may be relied upon for the only purpose for which we offer it, the purpose of this conclusion.

"The wisdom of the Creator," saith Hamburgher, "is in nothing seen more gloriously than in the heart." And how well doth it execute its office! An anatomist, who understood the structure of the heart, might say beforehand that it would play; but he would expect, I think, from the complexity of its mechanism, and the delicacy of many of its parts, that it should always be liable to derangement, or that it would soon work itself out. Yet shall this wonderful machine go, night and day, for eighty years together, at the rate of a hundred thousand strokes every twenty-four hours, having, at every stroke, a great resistance to overcome; and shall continue this action for this length of time, without disorder and without weariness!

But further; from the account which has been given of the mechanism of the heart, it is evident that it must require the interposition of *valves*; that the success indeed of its action

must depend upon these; for when any one of its cavities contracts, the necessary tendency of the force will be to drive the enclosed blood, not only into the mouth of the artery where it ought to go, but also back again into the mouth of the vein from which it flowed. In like manner, when by the relaxation of the fibres the same cavity is dilated, the blood would not only run into it from the vein, which was the course intended, but back from the artery, through which it ought to be moving forward. The way of preventing a reflux of the fluid, in both these cases, is to fix valves, which, like flood-gates, may open a way to the stream in one direction, and shut up the passage against it in another. The heart, constituted as it is, can no more work without valves than a pump can. When the piston descends in a pump, if it were not for the stoppage by the valve beneath, the motion would only thrust down the water which it had before drawn up. A similar consequence would frustrate the action of the heart. Valves, therefore, properly disposed, i.e. properly with respect to the course of the blood which it is necessary to promote, are essential to the contrivance. *And valves so disposed are accordingly provided.* A valve is placed in the communication between each

auricle and its ventricle, lest when the ventricle contracts, part of the blood should get back again into the auricle, instead of the whole entering, as it ought to do, the mouth of the artery. Valves are also fixed at the mouth of each of the great arteries which take the blood from the heart; leaving the passage free, so long as the blood holds its proper course forward; closing it, whenever the blood, in consequence of the relaxation of the ventricle, would attempt to flow back. There is some variety in the construction of these valves, though all the valves of the body act nearly upon the same principle, and are destined to the same use. In general they consist of a thin membrane, lying close to the side of the vessel, and consequently allowing an open passage whilst the stream runs one way, but thrust out from the side by the fluid getting behind it, and opposing the passage of the blood, when it would flow the other way. Where more than one membrane is employed, the different membranes only compose one valve. Their joint action fulfils the office of a valve: for instance, over the entrance of the right auricle of the heart into the right ventricle, three of these membranes are fixed, of a triangular figure, the bases of the triangles fastened to the flesh; the

sides and summits loose; but, though loose, connected by threads of a determinate length, with certain small fleshy prominences adjoining. The effect of this construction is that, when the ventricle contracts, the blood endeavouring to escape in all directions, and amongst other directions pressing upwards, gets *between* these membranes and the sides of the passage; and thereby forces them up into such a position as that, together, they constitute, when raised, a hollow cone (the strings, before spoken of, hindering them from proceeding or separating further); which cone, entirely occupying the passage, prevents the return of the blood into the auricle. A shorter account of the matter may be this:—So long as the blood proceeds in its proper course, the membranes which compose the valve are pressed close to the side of the vessel, and occasion no impediment to the circulation: when the blood would regurgitate, they are raised from the side of the vessel, and, meeting in the middle of its cavity, shut up the channel. Can any one doubt of contrivance here; or is it possible to shut our eyes against the proof of it?

This valve, also, is not more curious in its structure, than it is important in its office. Upon the play of the valve, even upon the pro-

portioned length of the strings or fibres which check the ascent of the membranes, depends, as it should seem, nothing less than the life itself of the animal. We may here likewise repeat, what we before observed concerning some of the ligaments of the body, that they could not be formed by any action of the parts themselves. There are cases in which, although good uses appear to arise from the shape or configuration of a part, yet that shape or configuration itself may seem to be modified by the action of the part, or by the action or pressure of adjoining parts. But valves could not be so formed. Action and pressure are all against them. The blood, in its proper course, has no tendency to produce such things; and, in its improper or reflected current, has a tendency to prevent their production. Whilst we see, therefore, the use and necessity of this machinery, we can look to no other account of its origin or formation than the intending mind of a Creator. Nor can we without admiration reflect, that such thin membranes, such weak and tender instruments, as these valves are, should be able to hold out for seventy or eighty years.

Here also we cannot consider but with gratitude, how happy it is that our vital motions are *involuntary*. We should have enough to do,

if we had to keep our hearts beating and our stomachs at work. Did these things depend, we will not say upon our effort, but upon our bidding, our care, or our attention, they would leave us leisure for nothing else. We must have been continually upon the watch, and continually in fear; nor would this constitution have allowed of sleep.

It might perhaps be expected, that an organ so precious, of such central and primary importance as the heart is, should be defended by *a case*. The fact is, that a membranous purse or bag, made of strong, tough materials, is provided for it; holding the heart within its cavity, sitting easily about it; guarding its substance, without confining its motion; and lubricated by a secretion just sufficient to keep the surface of the heart in a state of suppleness and moisture. How should such a loose covering be generated by the action of the heart? Does not the enclosing of it in such a sack show the care that has been taken of its preservation?

The chief use of the circulation of the blood (amongst other uses) is to distribute nourishment to the different parts of the body. How minute and multiplied the ramifications of the blood-vessels, for that purpose, are; and how thickly spread, over at least the superficies of the body,

is proved by the single observation, that we cannot prick the point of a pin into the flesh, without drawing blood, i. e. without finding a blood-vessel. Nor, internally, is their diffusion less universal. Blood-vessels run along the surface of membranes, pervade the substance of muscles, penetrate the bones. Even into every tooth we trace, through a small hole in the root, an artery to feed the bone, as well as a vein to bring back the spare blood from it; both which, with the addition of an accompanying nerve, form a thread only a little thicker than a horse-hair.

• Wherefore, when the nourishment, taken in at the mouth, has once reached and mixed itself with the blood, every part of the body is in the way of being supplied with it. And this introduces another grand topic, namely, the manner in which the aliment gets into the *blood*; which is a subject distinct from the preceding, and brings us to the consideration of another entire system of vessels.

II. For this necessary part of the animal economy an apparatus is provided, in a great measure capable of being, what anatomists call, demonstrated, that is, shown in the dead body; —and a line or course of conveyance, which we can pursue by our examinations.

First, the food descends by a wide passage into the intestines, undergoing two great preparations on its way; one, in the mouth by mastication and moisture,—(can it be doubted with what design the teeth were placed in the road to the stomach, or that there was choice in fixing them in this situation?) the other, by digestion in the stomach itself. Of this last surprising dissolution I say nothing; because it is chemistry, and I am endeavouring to display mechanism. The figure and position of the stomach (I speak all along with a reference to the human organ) are calculated for detaining the food long enough for the action of its digestive juice. It has the shape of the pouch of a bagpipe; lies across the body; and the chemical digestion of the food is aided by a gentle to and fro undulatory movement, produced by the contraction successively of different parts of the muscular coat of the stomach. When the food is sufficiently dissolved, the muscular ring of the pylorus, which guards the entrance into the bowel, is relaxed, and the contents of the stomach are allowed to enter the duodenum.

For the same reason that I omitted, for the present, offering any observation upon the digestive fluid, I shall say nothing concerning the bile or the pancreatic juice, further than to

observe upon the mechanism, viz. that from the glands in which these secretions are elaborated, pipes are laid into the first of the intestines, through which pipes the product of each gland flows into that bowel, and is there mixed with the aliment, as soon almost as it passes the stomach; adding also, as a remark, how grievously this same bile offends the stomach itself, if it happen to intrude into it.

Secondly, We have now the aliment in the intestines converted into pulp; and, though lately consisting of ten different viands, reduced to nearly an uniform substance, and to a state fitted for yielding its essence, which is called chyle. For the straining off this fluid from the digested aliment in the course of its long progress through the body, myriads of capillary tubes, i. e. pipes as small as hairs, open their orifices into the cavity of every part of the intestines. These tubes, which are so fine and slender as not to be visible unless when distended with chyle, soon unite into larger branches. The pipes, formed by this union, pass through glands, carrying the chyle from all parts into a common reservoir or *receptacle*. This receptacle is little more than a dilatation of the main duct, which itself scarcely exceeds a crow-quill in size: it climbs up the back part of the chest, and after-

wards creeps along the gullet till it reaches the neck. Here it meets the river; here it discharges itself into a large vein, which soon conveys the chyle, now flowing along with the old blood, to the heart. This whole route can be exhibited to the eye; nothing is left to be supplied by imagination or conjecture. Now, beside the subserviency of this structure, collectively considered, to a manifest and necessary purpose, we may remark two or three separate particulars in it, which show, not only the contrivance, but the perfection of it. We may remark, first, the length of the intestines, which, in the human subject, is nearly six times that of the body. Simply for a passage, these voluminous bowels seem in no wise necessary; but, in order to allow time and space for the successive extraction of the chyle from the digested aliment, namely, that the chyle, which escapes the lacteals of one part of the intestine, may be taken up by those of some other part, the length of the canal is of evident use and conduciveness. Secondly, we must also remark their peristaltic motion; which is made up of contractions, following one another like waves upon the surface of a fluid, and not unlike what we observe in the body of an earth-worm crawling along the ground; and which is effected by the joint action of longi-

tudinal and of spiral, or rather perhaps of a great number of separate, semicircular fibres. This curious action pushes forward the grosser part of the aliment, at the same time that the more subtle parts, which we call chyle, are absorbed by the narrow orifices of the lacteal vessels. Thirdly, it was necessary that these tubes, which we denominate lacteals, or their mouths at least, should be made as narrow as possible, in order to deny admission into the blood to any particle, which is of size enough to make a lodgment afterwards in the small arteries, and thereby to obstruct the circulation: And it was also necessary that this extreme tenuity should be compensated by multitude; for, a large quantity of chyle is, by some means or other, to be passed through them. Accordingly we find the number of the lacteals exceeding all powers of computation; and their pipes so fine and slender, as not to be visible, unless filled, to the naked eye; and their orifices, which open into the intestines, are of extreme minuteness. Fourthly, the main pipe, which carries the chyle from the reservoir to the blood, viz. the thoracic duct, being fixed in an almost upright position, and wanting that advantage of propulsion which the arteries possess, is furnished with a succession of valves to check the ascending fluid, when once it has

passed them, from falling back. These valves look upward, so as to leave the ascent free, but to prevent the return of the chyle, if, for want of sufficient force to push it on, its weight should at any time cause it to descend. Fifthly, the chyle enters the blood in an odd place, but perhaps the most commodious place possible, viz. at a large vein in the neck, so situated with respect to the circulation, as speedily to bring the mixture to the heart. And this seems to be a circumstance of great moment; for had the chyle entered the blood at an artery, or at a distant vein, the fluid, composed of the old and the new materials, must have performed a considerable part of the circulation, before its admixture with the blood, and transmission through the lungs. Who could have dreamt of a communication between the cavity of the intestines and the left great vein of the *neck*? Who could have suspected that this communication should be the medium through which all nourishment is derived to the body? or this the place, where, by a side-inlet, the important junction is formed between the blood and the material which feeds it!

We postponed the consideration of *digestion*, lest it should interrupt us in tracing the course of the food to the blood; but, in treating of

the alimentary system, so principal a part of the process cannot be omitted.

1. The gastric juice is not a simple diluent, but a real solvent. A quarter of an ounce of beef had scarcely touched the stomach of a crow, when the solution began.

2. It has not the nature of saliva ; it has not the nature of bile ; but is distinct from both. By experiments it appears, that neither of these secretions acts upon alimentary substances, in the same manner as the gastric juice acts, but each assists in the process of solution.

3. Digestion is not *putrefaction* ; for, the digesting fluid resists putrefaction most pertinaciously ; nay, not only checks its further progress, but restores putrid substances.

4. No fermentation occurs in healthy digestion, but a true solution of the food.

In a word, animal digestion carries about it the marks of being a power and a process completely *sui generis*. And the most wonderful thing about it is its appropriation ; its subserviency to the particular economy of each animal. The gastric juice of an owl, falcon, or kite, will not touch grain ; no, not even to finish the macerated and half-digested pulse which is left in the crops of the sparrows that the bird devours. In poultry, the trituration of the

gizzard, and the gastric juice, conspire in the work of digestion. The gastric juice will not dissolve the grain whilst it is whole. Entire grains of barley, enclosed in tubes or spherules, are not affected by it. But if the same grain be by any means broken or ground, the gastric juice immediately lays hold of it. Here then is wanted, and here we find, a combination of mechanism and chemistry. For the preparatory grinding, the gizzard lends its mill. And, as all mill-work should be strong, its structure is so, beyond that of any other muscle belonging to the animal. The internal coat also, or lining of the gizzard, is, for the same purpose, hard and cartilaginous. But, forasmuch as this is not the sort of animal substance suited for the reception of glands, or for secretion, the gastric juice, in this family, is not supplied as in membranous stomachs, by the stomach itself, but by the gullet, in which the feeding glands are placed, and from which it trickles down into the stomach.

In sheep, the gastric fluid has no effect in digesting plants, *unless they have been previously masticated*. It only produces a slight maceration; nearly such as common water would produce, in a degree of heat somewhat exceeding the medium temperature of the atmosphere.

But provided that the plant has been reduced to pieces by chewing, and mixed freely with the saliva, the gastric juice then proceeds with it, first by softening its substance; next, by destroying its natural consistency; and, lastly, by dissolving it so completely, as not even to spare the toughest and most stringy parts, such as the nerves of the leaves.

It has been shown that the gastric juice of the sheep and the ox speedily dissolved vegetables, but made no impression upon beef, mutton, and other animal bodies. John Hunter discovered a property of this fluid, of a most curious kind; viz. that, in the stomachs of animals which feed upon flesh, irresistibly as this fluid acts upon animal substances, it is only upon the *dead* substance that it operates at all. The *living* fibre suffers no injury from lying in contact with it. The coats of the human stomach, in a healthy state, are insensible to its presence: yet, in cases of sudden death (wherein the gastric juice, not having been weakened by disease, retains its activity), it has been known to eat a hole through the bowel which contains it. How nice is this discrimination of action, yet how necessary!

But to return to our hydraulics.

III. The gall-bladder is a very remarkable

contrivance. It is the reservoir of a canal. It does not form the channel itself, i. e. the direct communication between the liver and the intestine, but communicates with the former by an indirect channel, through which the bile is poured to be stored for future use. Thus, one duct proceeds from the liver to the intestine, and is joined, in its course thither, by another duct, the two uniting at an acute angle to form one common duct. Thus, during digestion, bile finds its way directly from the liver into the duodenum, and the current is joined, as required, by that from the gall-bladder. But when not required for digestion, the bile flows back into the gall-bladder, where it is stored and improved for future use.

The gall-bladder is seated against the duodenum, and thereby liable to have its fluid pressed out, by the passage of the aliment through that cavity; which likewise will have the effect of causing the bile to be received into the intestine, at a right time, and in a due proportion.

There may be other purposes answered by this contrivance; and it is probable that there are. The contents of the gall-bladder are not exactly of the same kind as what passes from the liver through the direct passage, but the

bile is rendered thicker, by the absorption of some of its watery part.

The entrance of the gall-duct into the duodenum furnishes another observation. Whenever either smaller tubes are inserted into larger tubes, or tubes into vessels and cavities, such receiving-tubes, vessels or cavities being subject to muscular constriction, we always find a contrivance to prevent *regurgitation*. In some cases, valves are used; in other cases, amongst which is that now before us, a different expedient is resorted to; which may be thus described. The gall-duct enters the duodenum obliquely: after it has pierced the first coat, it runs near two fingers' breadth *between* the coats, before it opens into the cavity of the intestine. The same contrivance is used in another part, where there is exactly the same occasion for it, viz. in the insertion of the ureters in the bladder. These enter the bladder near its neck, running obliquely for the space of an inch between its coats. It is, in both cases, sufficiently evident that this structure has a necessary mechanical tendency to resist regurgitation; for, whatever force acts in such a direction as to urge the fluid back into the orifices of the tubes, must, at the same time, stretch the coats of the vessels, and thereby compress that part of the

tube which is included between them : and this most effectively when the bladder is distended.

IV. Amongst the *vessels* of the human body, the pipe which conveys the saliva from the place where it is made to the place where it is wanted, deserves to be reckoned amongst the most intelligible pieces of mechanism with which we are acquainted. The saliva, we all know, is used in the mouth ; but much of it is produced on the outside of the cheek, by the parotid gland, which lies between the ear and the angle of the lower jaw. In order to carry the secreted juice to its destination, there is, laid from the gland on the outside, a pipe about the thickness of a wheat straw, and about three fingers' breadth in length ; which, after riding over the masseter muscle, bores for itself a hole through the very middle of the cheek ; enters obliquely, i. e. in a valvular form, by that hole, which is a complete perforation of the buccinator muscle, into the mouth ; and there discharges its fluid very copiously.

V. Another exquisite structure, differing indeed from the four preceding instances in that it does not relate to the conveyance of fluids, but still belonging, like these, to the class of pipes or conduits of the body, is seen in the *larynx*. We all know that there go down the

throat two pipes, one leading to the stomach, the other to the lungs; the one being the passage for the food, the other for the breath and voice: we know also that both these passages open into the bottom of the mouth; the gullet, necessarily, for the conveyance of food; and the wind-pipe for speech and the modulation of sound, not much less so: therefore the difficulty was, the passages being so contiguous, to prevent the food, especially the liquids which we swallow into the stomach, from entering the wind-pipe, i. e. the road to the lungs; the consequence of which error, when it does happen, is perceived by the convulsive throes that are instantly produced. This business, which is very nice, is managed in this manner. The gullet (the passage for food) opens into the mouth like the cone or upper part of a funnel, the capacity of which forms indeed the bottom of the mouth. In front of this funnel enters the wind-pipe, by a chink or slit, with a lid or flap, like a little trap-door, accurately fitted to the orifice. The solids or liquids which we swallow pass over this lid or flap, as they descend by the funnel into the gullet. Both the weight of the food, and the action of the tongue and muscles concerned in swallowing, contribute to keep the lid close down upon the aperture, whilst anything

is passing ; and this is aided by the elevation of the larynx : but when the act of swallowing is completed, and the tongue is brought forward in the mouth, the air-tube is again opened, and a free inlet and outlet for the respiration of air by the lungs is provided. Such is its structure : And we may here remark the almost complete success of the expedient, viz. how seldom it fails of its purpose compared with the number of instances in which it fulfils it. Reflect how frequently we swallow, how constantly we breathe. In a city-feast, for example, what deglutition, what anhelation ! yet does this little cartilage, the epiglottis, so effectually interpose its office, so securely guard the entrance of the wind-pipe, that whilst morsel after morsel, draught after draught, are coursing one another over it, an accident of a crumb or a drop slipping into this passage (which nevertheless must be opened for the breath every second of time) excites in the whole company, not only alarm by its danger, but surprise by its novelty. Not two guests are choked in a century.

Not only is the larynx curious, but the whole wind-pipe possesses a structure adapted to its peculiar office. It is made up (as any one may perceive by putting his fingers to his throat) of stout cartilaginous rings, placed at small and

equal distances from one another. Now, this is not the case with any other of the numerous conduits of the body. The use of these cartilages is to keep the passage for the air *constantly* open, which they do mechanically. A pipe with soft membranous coats, liable to collapse and close when empty, would not have answered here; although this is the general vascular structure, and a structure which serves very well for those tubes which are kept in a state of perpetual distension by the fluid they enclose, or which afford a passage to solid and protruding substances.

Nevertheless (which is another particularity well worthy of notice), these rings are not complete, that is, are not cartilaginous and stiff all round; but their hinder part, which is contiguous to the gullet, is membranous and soft, easily yielding to the distensions of that organ occasioned by the descent of solid food. The same rings are connected by membrane, the better to close upon one another, when the trachea is compressed or shortened.

The constitution of the larynx may suggest likewise another reflection. The membrane which lines its inside is, especially at its orifice, perhaps, the most sensible, irritable membrane of the body. It rejects the touch of a crumb of

bread, or a drop of water, with a spasm which convulses the whole frame; yet, left to itself, and its proper office, the intrömission of air alone, nothing can be so quiet. It does not even make itself felt; a man does not know that he has a trachea. This capacity of perceiving with such acuteness, this impatience of offence, yet perfect rest and ease when let alone, are properties, one would have thought, not likely to reside in the same subject. It is to the junction, however, of these almost inconsistent qualities, in this, as well as in some other delicate parts of the body, that we owe our safety and our comfort;—our safety to their sensibility, our comfort to their repose.

The larynx, or rather the whole wind-pipe taken together (for the larynx is only the upper part of the wind-pipe), besides its other uses, is also a musical instrument, that is to say, it is *mechanism* expressly adapted to the modulation of sound; for it has been found upon trial that, by relaxing or tightening the tendinous bands at the extremity of the wind-pipe, and blowing in at the other end, all the cries and notes might be produced of which the living animal was capable. It can be sounded, just as a pipe or flute is sounded.

In singing birds the muscular apparatus at

the lower part of the wind-pipe is very complex, for the production of various notes and the modulation of sound.

The use of the lungs *in* the system has been noticed elsewhere ; another use, though, in some sense, external to the system, is the formation, in conjunction with the larynx, of voice and speech. The lungs are, to animal utterance, what the bellows are to the organ.

FOR the sake of method, we have considered animal bodies under three divisions ; their bones, their muscles, and their vessels : and we have stated our observations upon these parts separately. But this is to diminish the strength of the argument. The wisdom of the Creator is seen, not in their separate but their collective action ; in their mutual subserviency and dependence ; in their contributing *together* to one effect, and one use. It has been said, that a man cannot lift his hand to his head, without finding enough to convince him of the existence of a God. And it is well said ; for he has only to reflect, familiar as this action is, and simple as it seems to be, how many things are requisite for the performing of it : how many things which we understand, to say nothing of many more, probably, which we do not ; viz. first a

long, hard, strong cylinder, in order to give to the arm its firmness and tension ; but which, being rigid, and in its substance inflexible, can only turn upon joints: secondly, therefore, joints for this purpose, one at the shoulder to raise the arm, another at the elbow to bend it : these joints continually fed with a soft mucilage to make the parts slip easily upon one another, and holden together by strong braces, to keep them in their position : then, thirdly, strings and wires, i. e. muscles and tendons, artificially inserted for the purpose of drawing the bones in the directions in which the joints allow them to move. Hitherto we seem to understand the mechanism pretty well ; and understanding this, we possess enough for our conclusion : nevertheless, we have hitherto only a machine standing still ; a dead organization,—an apparatus. To put the system in a state of activity, to set it at work, a further provision is necessary, viz. a communication with the brain by means of nerves. We know the existence of this communication, because we can see the communicating threads, and can trace them to the brain ; its necessity we also know, because if the thread be cut, if the communication be intercepted, the muscle becomes paralytic.

To what has been enumerated, as officiating

in the single act of a man's raising his hand to his head, must be added likewise, all that is necessary, and all that contributes to the growth, nourishment, and sustentation of the limb, the repair of its waste, the preservation of its health: such as the circulation of the blood through every part of it; its lymphatics, exhalants, absorbents; its excretions and integuments. All these share in the result; join in the effect: and how all these, or any of them, come together without a designing, disposing intelligence, it is impossible to conceive.

## CHAPTER XI.

### OF THE ANIMAL STRUCTURE REGARDED AS A MASS.

CONTEMPLATING *an animal body* in its collective capacity, we cannot forget to notice what a number of instruments are brought together, and often within how small a compass. It is a cluster of contrivances. In a canary bird, for instance, and in the single ounce of matter which composes his body (but which seems to be all employed), we have instruments for eating, for digesting, for nourishment, for breathing, for generation, for running, for flying, for seeing, for hearing, for smelling; each appropriate,—each entirely different from all the rest.

The human, or indeed the animal frame, considered as a mass or assemblage, exhibits in its composition three properties, which have long struck my mind as indubitable evidences, not only of design, but of a great deal of attention and accuracy in prosecuting the design.

1. The first is, the exact correspondency of the two sides of the same animal; the right hand answering to the left, leg to leg, eye to eye, one side of the countenance to the other; and with a precision, to imitate which in any tolerable degree forms one of the difficulties of statuary, and requires, on the part of the artist, a constant attention to this property of his work, distinct from every other.

It is the most difficult thing that can be to get a wig made even; yet how seldom is the *face awry!* And what care is taken that it should not be so, the anatomy of its bones demonstrates. The bones exclusively belonging to the face are six pairs, and two single ones in the centre, including the lower jaw. In building an arch, could more be done in order to make the curve *true*, i. e. the parts equi-distant from the middle, alike in figure and position?

The exact resemblance of the *eyes*, considering how compounded this organ is in its structure, how various and how delicate are the shades of colour with which its iris is tinged, how differently, as to effect upon appearance, the eye may be mounted in its socket, and how differently in different heads eyes actually are set, is a property of animal bodies much to be admired. Of ten thousand eyes, I do not know

that it would be possible to match one, except with its own fellow ; or to distribute them into suitable pairs by any other selection than that which obtains.

This regularity of the animal structure is rendered more remarkable by the three following considerations :—First, the limbs, *separately* taken, have not this correlation of parts, but the contrary of it. A knife drawn down the chine cuts the human body into two parts, externally equal and alike ; you cannot draw a straight line which will divide a hand, a foot, the leg, the thigh, the cheek, the eye, the ear, into two parts equal and alike. Those parts which are placed upon the middle or partition line of the body, or which traverse that line, as the nose, the tongue, the lips, may be so divided, or, more properly speaking, are double organs ; but other parts cannot. This shows that the correspondence, which we have been describing, does not arise by any necessity in the nature of the subject : for, if necessary, it would be universal ; whereas it is observed only in the system or assemblage : it is not true of the separate parts ; that is to say, it is found where it conduces to beauty or utility ; it is not found where it would subsist at the expense of both. The two wings of a bird always correspond : the

two sides of a feather frequently do not. In centipedes, millepedes, and that whole tribe of insects, no two legs on the same side are alike: yet there is the most exact parity between the legs opposite to one another.

2. The next circumstance to be remarked is, that whilst the cavities of the body are so configurated, as *externally* to exhibit the most exact correspondency of the opposite sides, the contents of these cavities have no such correspondency. A line drawn down the middle of the breast divides the thorax into two sides exactly similar; yet these two sides enclose very different contents. The heart points towards the left side; an extra lobe of the lungs is on the right; balancing each other, neither in size nor shape. The same thing holds of the abdomen. The liver lies on the right side, without any similar viscus opposed to it on the left. The spleen indeed is situated over against the liver; but agreeing with the liver neither in bulk nor form. There is no equipollency between these. The stomach is a vessel, both irregular in its shape, and oblique in its position. The foldings and doublings of the intestines do not present a parity of sides. Yet that symmetry, which depends upon the correlation of the sides, is externally preserved throughout the whole

trunk ; and is the more remarkable in the lower parts of it, as the integuments are soft ; and the shape consequently is not as the thorax is by its ribs, reduced by natural stays. It is evident, therefore, that the external proportion does not arise from any equality in the shape or pressure of the internal contents. What is it indeed but a correction of inequalities ? an adjustment, by mutual compensation, of anomalous forms into a regular congeries ? the effect, in a word, of artful, and, if we might be permitted so to speak, of studied collocation ?

3. Similar also to this is the third observation ; that an internal inequality in the feeding vessels is so managed, as to produce no inequality in parts which were intended to correspond. The right arm answers accurately to the left, both in size and shape ; but the arterial branches, which supply the two arms, do not go off from their trunk in a pair, in the same manner, at the same place, or at the same angle. Under which want of similitude the two limbs, which are nourished by them, perceive no difference of supply, no effects of excess or deficiency.

II. Another perfection of the animal mass is the *package*. I know nothing which is so surprising. Examine the contents of the trunk of

any large animal. Take notice how soft, how tender, how intricate they are; how constantly in action, how necessary to life! Reflect upon the danger of any injury to their substance, any derangement of their position, any obstruction to their office. Observe the heart pumping at the centre, at the rate of eighty strokes in a minute: one set of pipes carrying the stream away from it, another set bringing, in its course, the fluid back to it again; the lungs performing their elaborate office, viz. distending and contracting their many thousand vesicles, by a reciprocation which cannot cease for a minute; the stomach exercising its powerful chemistry; the bowels silently propelling the changed aliment; collecting from it, as it proceeds, and transmitting to the blood, an incessant supply of prepared and assimilated nourishment; the blood pursuing its course; the liver, the kidneys, the pancreas, the parotid, with many other known and distinguishable glands, drawing off from it, all the while, their proper secretions. These several operations, together with others more subtle but less capable of being investigated, are going on within us, at one and the same time. Think of this; and then observe how the body itself, the case which holds this machinery, is rolled, and jolted, and tossed

about, the mechanism remaining unhurt, and with very little molestation even of its nicest motions. Observe a rope-dancer, a tumbler, or a monkey; the sudden inversions and contortions which the internal parts sustain by the postures into which their bodies are thrown; or rather observe the shocks which these parts, even in ordinary subjects, sometimes receive from falls and bruises, or by abrupt jerks and twists, without sensible, or with soon-recovered damage. Observe this, and then reflect how firmly every part must be secured, how carefully surrounded, how well tied down and packed together.

This property of animal bodies has never, I think, been considered under a distinct head, or so fully as it deserves. I may be allowed, therefore, in order to verify my observation concerning it, to set forth a short anatomical detail, though it oblige me to use more technical language than I should wish to introduce into a work of this kind.

1. The *heart* (such care is taken of the centre of life) is placed between two soft lobes of the lungs, and is surrounded and protected by a dense membranous bag, the pericardium, which adheres to the diaphragm, and is smooth and lubricated in its interior. The great blood-

vessels, which issue from the heart, also assist in sustaining it in its place.

The lungs are in like manner held in position by the air-tubes passing into them, and by the great vessels passing into and out of them: there is also a delicate membrane, the pleura, surrounding each lung, and reflected over the interior of the chest walls, thus allowing of the free gliding movement, which is so essential in the alternate inflation and emptying of the lungs in breathing. Beyond the connexions mentioned, these organs lie quite loose and free within the chest, to the walls of which they are accurately fitted.

The liver, spleen, stomach, and other viscera contained in the abdominal cavity, are all so arranged and supported in their positions as to secure them from injury, and from interfering with each other in the performance of their several functions. A delicate membrane, similar to the pleura, and called the peritoneum, covers and holds down all the viscera, and lines the abdominal walls; its smooth surface, always kept moist by its own secretion, allows of the necessary gliding movements of the stomach and intestines over each other, and of other changes in position depending on movements of the body and on the acts of respiration.

2. The septa of the brain probably prevent one part of that organ from pressing with too great a weight upon another part. The processes of the dura mater divide the cavity of the skull, like so many inner partition walls, and thereby, with the irregular floor of the skull itself, confine each hemisphere and lobe of the brain to the chamber which is assigned to it, without its being liable to rest upon, or intermix with the neighbouring parts. The great art and caution of packing is to prevent one thing hurting another. This, in the head, the chest, and the abdomen of an animal body is, amongst other methods, provided for by membranous partitions and wrappings, which keep the parts separate.

The above may serve as a short account of the manner in which the principal viscera are sustained in their places. But of the provisions for this purpose, by far, in my opinion, the most curious, and where also such a provision was most wanted, is in the intestines. It is pretty evident that a long narrow tube (in man, about five times the length of the body) laid from side to side in folds upon one another, winding in oblique and circuitous directions, composed also of a soft and yielding substance, must, without some extraordinary precaution

for its safety, be continually displaced by the various, sudden, and abrupt motions of the body which contains it. I should expect that, if not bruised or wounded by every fall, or leap, or twist, it would be entangled, or be involved with itself; or, at the least, slipped and shaken out of the order in which it is disposed, and which order is necessary to be preserved for the carrying on of the important functions which it has to execute in the animal economy. Let us see, therefore, how a danger so serious, and yet so natural to the length, narrowness, and tubular form of the part, is provided against. The expedient is admirable; and it is this. The intestinal canal, throughout a great part of its length, is knit to the edge of a broad membrane, a part of the peritoneum, called the mesentery. It forms the margin of this mesentery, being fastened to it like the edging of a ruffle: being four times as long as the mesentery itself, it is what a sempstress would call, "puckered or gathered on" to it. This is the nature of the connexion of the gut with the mesentery; and being thus joined to, or rather made a part of, the mesentery, it is folded and wrapped up together with it. Now the mesentery, having a considerable dimension in breadth, being in its substance, withal, of con-

siderable strength, is capable of a close and safe folding, in comparison of what the intestinal tube would admit of, if it had remained loose. The mesentery likewise not only keeps the intestinal canal in its proper place and position under all the turns and windings of its course, but sustains the numberless small vessels, the arteries, the veins, the nerves, and, above all, the lacteals, which lead from or to almost every point of its coats and cavity.

III. A third general property of animal forms is *beauty*. I do not mean relative beauty, or that of one individual above another of the same species, or of one species compared with another species; but I mean, generally, the provision which is made in the body of almost every animal, to adapt its appearance to the perception of the animals with which it converses. In our own species, for example, only consider what the parts and materials are, of which the fairest body is composed; and no further observation will be necessary to show how well these things are wrapped up, so as to form a mass, which shall be capable of symmetry in its proportion, and of beauty in its aspect; how the bones are covered, the bowels concealed, the roughnesses of the muscle smoothed and softened; and how over the whole is drawn

an integument, which converts the disgusting materials of a dissecting-room into an object of attraction to the sight, or one upon which it rests, at least, with ease and satisfaction. Much of this effect is to be attributed to the intervention of the cellular and adipose membrane, which lies immediately under the skin; is a kind of lining to it; is moist, soft, elastic, and compressible; everywhere filling up the interstices of the muscles, and forming thereby their roundness and flowing line, as well as the evenness and polish of the whole surface.

All which seems to be a strong indication of design, and of a design studiously directed to this purpose. And it being once allowed, that such a purpose existed with respect to *any* of the productions of nature, we may refer, in a measure, with a considerable degree of probability, other particulars to the same intention; such as the tints of flowers, the plumage of birds, the furs of beasts, the bright scales of fishes, the painted wings of butterflies and beetles, the rich colours and spotted lustre of many tribes of insects.

There are parts also of animals ornamental, besides subserving other and more important purposes. The *irides* of most animals are very beautiful; and nature could in no part have

employed her pencil to so much advantage, because no part presents itself so conspicuously to the observer, or communicates so great an effect to the whole aspect.

In plants, especially in the flowers of plants, the principle of beauty holds a still more considerable place in their composition; is still more confessed than in animals. For, although we may believe that this profusion and brilliancy of colour, in all its rich variety, has an useful purpose, we know that it is calculated to please the eye by its beauty, and therefore we may reasonably conclude that it was intended also for display.

A ground, I know, of objection has been taken against the whole topic of argument, namely, that there is no such thing as beauty at all; in other words, that whatever is useful and familiar, comes of course to be thought beautiful; and that things appear to be so, only by their alliance with these qualities. Our idea of beauty is capable of being in so great a degree modified by habit, by fashion, by the experience of advantage or pleasure, and by associations arising out of that experience, that a question has been made, whether it be not altogether generated by these causes, or would have any proper existence without them. It

seems, however, a carrying of the conclusion too far, to deny the existence of the principle, viz. a native capacity of perceiving beauty, on account of an influence, or of varieties proceeding from that influence, to which it is subject; seeing that principles the most acknowledged are liable to be affected in the same manner. I should rather argue thus. The question respects objects of sight. Now every other sense hath its distinction of agreeable and disagreeable. Some tastes offend the palate, others gratify it. In brutes and insects, this distinction is stronger and more regular than in man. Every horse, ox, sheep, swine, when at liberty to choose, and when in a natural state, that is, when not vitiated by habits forced upon it, eats and rejects the same plants. Many insects, which feed upon particular plants, will rather die than change their appropriate leaf. All this looks like a determination in the sense itself to particular tastes. In like manner, smells affect the nose with sensations pleasurable or disgusting. Some sounds, or compositions of sound, delight the ear; others torture it. Habit can do much in all these cases (and it is well for us that it can; for it is this power which reconciles us to many necessities): but has the distinction, in the mean time, of agree-

able and disagreeable no foundation in the sense itself? What is true of the other senses, is most probably true of the eye (the analogy is irresistible), viz. that there belongs to it an original constitution, fitted to receive pleasure from some impressions, and pain from others. Yet these impressions on the senses depend very much on mental associations with them, and are greatly influenced by education. In many instances also, especially in the senses of smell, taste, and touch, the effects of impressions from without are designed for protection from that which would be injurious, if not avoided as offensive.

I do not however know, that the argument which alleges beauty as a final cause, rests upon the concession to which I have referred. We possess a sense of beauty, however we come by it. It in fact exists. Things are not indifferent to this sense; all objects do not suit it; many, which we see, are agreeable to it; many others disagreeable. It is certainly not the effect of habit upon the particular object, because the most agreeable objects are often the most rare; many, which are very common, continue to be offensive. If they be made supportable by habit, it is all which habit can do; they never become agreeable. If this sense,

therefore, be acquired, it is a result; the produce of numerous and complicated actions of external objects upon the senses, and of the mind upon its sensations. With this *result*, there must be a certain congruity to enable any particular object to please: and that congruity, we contend, is consulted in the *aspect* which is given to animal and vegetable bodies.

IV. The skin and covering of animals is that upon which their appearance chiefly depends, and it is that part which, perhaps, in all animals is most decorated, and most free from impurities. But were beauty, or agreeableness of aspect, entirely out of the question, there is another purpose answered by this integument, and by the collocation of the parts of the body beneath it, which is of still greater importance; and that purpose is *concealment*. Were it possible to view through the skin the mechanism of our bodies, the sight would frighten us out of our wits. “Durst we make a single movement,” asks a lively French writer, “or stir a step from the place we were in, if we *saw* our blood circulating, the tendons pulling, the lungs blowing, the humours filtrating, and all the incomprehensible assemblage of fibres, tubes, pumps, valves, currents, pivots, which sustain an existence at once so frail, and so presumptuous?”

V. Of animal bodies, considered as masses, there is another property, more curious than it is generally thought to be; which is the faculty of *standing*; and it is more remarkable in two-legged animals than in quadrupeds, and, most of all, as being the tallest, and resting upon the smallest base, in man. There is more, I think, in the matter than we are aware of. The statue of a man, placed loosely upon its pedestal, would not be secure of standing half an hour. You are obliged to fix its feet to the block by bolts and solder; or the first shake, the first gust of wind, is sure to throw it down. Yet this statue shall express all the mechanical proportions of a living model. It is not therefore the mere figure, or merely placing the centre of gravity within the base, that is sufficient. Either the law of gravitation is suspended in favour of living substances, or something more is done for them, in order to enable them to uphold their posture. There is no reason whatever to doubt, but that their parts descend by gravitation in the same manner as those of dead matter. The gift, therefore, appears to me to consist in a faculty of poising the superincumbent weight of the body upon and around a perpetually shifting centre of gravity, by a set of obscure, indeed, but of quick-balancing actions, so as to keep

the line of direction, which is a line drawn from that centre to the ground, within its prescribed limits. Of these actions it may be observed, first, that they in part constitute what we call strength, i.e. muscular action. The dead body drops down. The mere adjustment therefore of weight and pressure, which may be the same the moment after death as the moment before, does not support the column. In cases also of extreme weakness, the patient cannot stand upright. Secondly, that these actions are only in a small degree voluntary; i.e. the exercise of volition has become so habitual that we are not conscious of it. A man is seldom conscious of his voluntary powers in keeping himself upon his legs. A child learning to walk is the greatest posture-master in the world: but art, if it may be so called, sinks into habit; and he is soon able to poise himself in a great variety of attitudes, without being sensible either of caution or effort. But still there must be an aptitude of parts, upon which habit can thus attach; a previous capacity of motions which the animal is thus taught to exercise: and the facility with which this exercise is acquired forms one object of our admiration. What parts are principally employed, or in what manner each contributes its office, is, as hath already

been confessed, difficult to explain. Perhaps the obscure motion of the bones of the feet may have their share in this effect. They are put in action by every slip or vacillation of the body and seem to assist in restoring its balance. Certain it is, that this circumstance in the structure of the foot, viz. its being composed of many small bones, applied to, and articulating with one another, by diversely-shaped surfaces, instead of being made of one piece, like the last of a shoe, is very remarkable. I suppose also, that it would be difficult to stand firmly upon stilts or wooden legs, though their base exactly imitated the figure and dimensions of the sole of the foot. The alternation of the joints, the knee-joint bending backward, the ankle and hip-joints forward; the flexibility, in every direction, of the spine; appear to be of great moment in preserving the equilibrium of the body. With respect to this last circumstance it is observable, that the vertebræ are so confined by the form of their joints and by ligaments, as to allow no more slipping upon one another, than what is just sufficient to admit of slight bending, or to break the shock which any violent motion may occasion to the body. A certain degree also of action of the muscles appears to be essential to an erect posture; for

it is by the loss of this, that the dead or paralytic body drops down. The whole is a wonderful result of combined powers, and of very complicated operations. Indeed, that *standing* is not so simple a business as we imagine it to be, is evident from the strange gesticulations of a drunken man, who has lost the government of the centre of gravity.

We have said that this property is the most worthy of observation in the *human* body: but a *bird*, resting upon its perch, or hopping upon a spray, affords no mean specimen of the same faculty. A chicken runs off as soon as it is hatched from the egg; yet a chicken, considered geometrically, and with relation to its centre of gravity, its line of direction, and its equilibrium, is a very irregular solid. Is this gift, therefore, or instruction? May it not be said to be with great attention, that nature hath balanced the body upon its pivots?

I observe also in the same *bird*, a piece of useful mechanism of this kind. In the trussing of a fowl, upon bending the legs and thighs up towards the body, the cook finds that the claws close of their own accord. Now let it be remembered, that this is the position of the limbs in which the bird rests upon its perch. And in this position it sleeps in safety; for the claws

do their office in keeping hold of the support, not by any exertion of voluntary power, which sleep might suspend, but by the traction of the tendons in consequence of the angular attitude which the legs and thighs take by the bird sitting down, and to which the mere weight of the body gives the force that is necessary.

VI. Regarding the human body as a mass; regarding the general conformations which obtain in it; regarding also particular parts in respect to those conformations; we shall be led to observe what I call "interrupted analogies." The following are examples of what I mean by these terms; and I do not know how such critical deviations can, by any possible hypothesis, be accounted for without design.

1. All the bones of the body are covered with a *periosteum*, except the teeth, where it ceases, and an enamel of ivory, which saws and files will hardly touch, comes into its place. No one can doubt of the use and propriety of this difference; of the "analogy" being thus "interrupted;" of the rule, which belongs to the conformation of the bones, stopping where it does stop: for, had so exquisitely sensitive a membrane as the periosteum invested the teeth, as it invests every other bone of the body, their action, necessary exposure, and irritation, would

have subjected the animal to continual pain. General as it is, it was not the sort of integument which suited the teeth; what they stood in need of, was a strong, hard, insensible, defensive coat: and exactly such a covering is given to them, in the ivory enamel which adheres to their surface.

2. The scarf-skin, which clothes all the rest of the body, gives way, at the extremities of the toes and fingers, to *nails*. A man has only to look at his hand, to observe with what nicety and precision that covering, which extends over every other part, is here superseded by a different substance, and a different texture. Now, if either the rule had been necessary, or the deviation from it accidental, this effect would not be seen. When I speak of the rule being necessary, I mean the formation of the skin upon the surface being produced by a set of causes constituted without design, and acting, as all ignorant causes must act, by a general operation. Were this the case, no account could be given of the operation being suspended at the fingers' ends, or on the back part of the fingers, and not on the fore part. On the other hand, if the deviation were accidental, an error, an anomalous; were it anything else than settled by intention; we should meet

with nails upon other parts of the body. They would be scattered over the surface, like warts or pimples.

3. All the great cavities of the body are enclosed in part or almost entirely by membranous walls, except the *skull*. Why should not the brain be content with the same covering as that which serves for the other principal organs of the body? I can see a reason for this distinction in the final cause, but in no other. The importance of the brain to life (which experience proves to be immediate), and the extreme tenderness of its substance, make a solid case more necessary for it than for any other part: and such a case the hardness and arched form of the skull supply. If an anatomist should say, that this bony protection is not confined to the brain, but is extended along the course of the spine, I answer, that he adds strength to the argument. If he remark, that the chest also is fortified by bones, I reply that I should have alleged this instance myself, if the ribs had not appeared subservient to the purpose of motion as well as of defence. What distinguishes the skull from every other cavity is, that the bony covering completely surrounds its contents, and is calculated, not for motion, but solely for defence. Those

hollows, likewise, and inequalities, which we observe in the inside of the skull, exactly fit the corresponding inequalities of the brain, and thus keep it steady, and guard it against concussions.

## CHAPTER XII.

## COMPARATIVE ANATOMY.

WHENEVER we find a general plan pursued, yet with such variations in it as are, in each case, required by the particular exigency of the subject to which it is applied, we possess, in such plan and such adaptation, the strongest evidence that can be afforded of intelligence and design ; an evidence which most completely excludes every other hypothesis. If the general plan proceeded from any fixed necessity in the nature of things, how could it accommodate itself to the various wants and uses which it had to serve under different circumstances and on different occasions ? *Arkwright's* mill was invented for the spinning of cotton. We see it employed for the spinning of wool, flax, and hemp, with such modifications of the original principle, such variety in the same plan, as the texture of those different materials rendered necessary. Of the

machine's being put together with design if it were possible to doubt, whilst we saw it only under one mode, and in one form; when we came to observe it in its different applications, with such changes of structure, such additions and supplements, as the special and particular use in each case demanded, we could not refuse any longer our assent to the proposition, "that intelligence, properly and strictly so called (including under that name foresight, consideration, reference to utility), had been employed, as well in the primitive plan, as in the several changes and accommodations which it is made to undergo."

Very much of this reasoning is applicable to what has been called *Comparative Anatomy*. In their general economy, in the outlines of the plan, in the construction as well as offices of their principal parts, there exists between all large terrestrial animals a close resemblance. In all life is sustained, and the body nourished, by nearly the same apparatus. The heart, the lungs, the stomach, the liver, the kidneys, are much alike in all. The same fluid (for no important distinction of blood has been observed) circulates through their vessels, and nearly in the same order. The same cause, therefore, whatever that cause was, has been

---

concerned in the origin, has governed the production of these different animal forms.

When we pass on to smaller animals, or to the inhabitants of a different element, the resemblance becomes more distant and more obscure ; but still the plan accompanies us.

And, what we can never enough commend, and which it is our business at present to exemplify, the plan is attended, through all its varieties and deflections, by subserviences to special occasions and utilities.

I. The *covering* of different animals (though whether I am correct in classing this under their anatomy, I do not know) is the first thing which presents itself to our observation ; and is in truth, both for its variety, and its suitableness to their several natures, as much to be admired as any part of their structure. We have bristles, hair, wool, furs, feathers, quills, prickles, scales ; yet in this diversity both of material and form, we cannot change one animal's coat for another, without evidently changing it for the worse : taking care, however, to remark, that these coverings are, in many cases, armour as well as clothing ; intended for protection as well as warmth.

The *human* animal is the only one which is naked, and the only one which can clothe

itself. This is one of the properties which renders him an animal of all climates, and of all seasons. He can adapt the warmth or lightness of his covering to the temperature of his habitation. Had he been born with a fleece upon his back, although he might have been comforted by its warmth in high latitudes, it would have oppressed him by its weight and heat, as the species spread towards the equator.

What art, however, does for men, nature has, in many instances, done for those animals which are incapable of art. Their clothing, of its own accord, changes with their necessities. This is particularly the case with that large tribe of quadrupeds which are covered with *furs*. Every dealer in hare-skins and rabbit-skins knows how much the fur is thickened by the approach of winter. It seems to be a part of the same constitution and the same design, that wool, in hot countries, degenerates, as it is called, but in truth (most happily for the animal's ease) passes into hair; whilst, on the contrary, that hair, on the dogs of the polar regions, is turned into wool, or something very like it. To which may be referred what naturalists have remarked, that bears, wolves, foxes, hares, which do not take the water, have the fur much thicker on the back than the belly; whereas on

the beaver it is the thickest upon the belly ; as are the feathers on water-fowl. We know the final cause of all this ; and we know no other.

THE ARGUS PHEASANT, ETC.

Given as examples of plumage, elaborate in structure, and rich in decoration.

The *covering of birds* cannot escape the most vulgar observation. Its lightness, its

smoothness, its warmth;—the disposition of the feathers all inclined backward, the down about their stem, the overlapping of their tips, their different configuration in different parts, not to mention the variety of their colours, constitute a vestment for the body, so beautiful, and so appropriate to the life which the animal is to lead, as that, I think, we should have had no conception of anything equally perfect, if we had never seen it, or can now imagine anything more so. Let us suppose (what is possible only in supposition) a person who had never seen a bird, to be presented with a plucked pheasant, and bid to set his wits to work, how to contrive for it a covering which shall unite the qualities of warmth, levity, and least resistance to the air, and the highest degree of each; giving it also as much of beauty and ornament as he could afford. He is the person to behold the work of the Deity, in this part of His creation, with the sentiments which are due to it.

The commendation, which the general aspect of the feathered world seldom fails of exciting, will be increased by further examination. It is one of those cases in which the philosopher has more to admire than the common observer. Every *feather* is a mechanical wonder. If we

---

look at the quill, we find properties not easily brought together,—strength and lightness. I know few things more remarkable than the strength and lightness of the very pen with which I am writing. If we cast our eye to the upper part of the stem, we see a material, made for the purpose, used in no other class of animals, and in no other part of birds ; tough, light, pliant, elastic. The pith, also, which occupies the interior of this part, preserves the form, without adding much to the weight, of the feather.

But the artificial part of a feather is the *beard*, or, as it is sometimes I believe called, the *vane*. By the beards are meant what are fastened on each side of the stem, and what constitute the breadth of the feather ; what we usually strip off from one side or both, when we make a pen. The separate pieces, or *laminæ*, of which the beard is composed, are called *threads*, sometimes *filaments*, or *rays*. Now the first thing which an attentive observer will remark is, how much stronger the beard of the feather shows itself to be, when pressed in a direction perpendicular to its plane, than when rubbed, either up or down, in the line of the stem ; and he will soon discover the structure which occasions this difference ; viz. that the

laminæ whereof these beards are composed are flat, and placed with their flat sides towards each other ; by which means, whilst they *easily* bend for the approaching of each other, as any one may perceive by drawing his finger ever so lightly upwards, they are much harder to bend out of their plane, which is the direction in which they have to encounter the impulse and pressure of the air, and in which their strength is wanted and put to the trial.

This is one particularity in the structure of a feather ; a second is still more extraordinary. Whoever examines a feather cannot help taking notice that the threads or laminæ, of which we have been speaking, in their natural state *unite* ; that their union is something more than the mere apposition of loose surfaces ; that they are not parted asunder without some degree of force ; that nevertheless there is no glutinous cohesion between them ; that, therefore, by some mechanical means or other, they catch or clasp among themselves, thereby giving to the beard or vane its closeness and compactness of texture. Nor is this all : when two laminæ, which have been separated by accident or force, are brought together again, they immediately *reclasp* ; the connexion is perfectly recovered, and the beard of the

feather becomes as smooth and firm as if nothing had happened to it. Draw your finger down the feather, which is against the grain, and you break probably the junction of some of the contiguous threads; draw your finger up the feather, and you restore all things to their former state. This is no common contrivance: and now for the mechanism by which it is effected. The threads or laminæ, above mentioned, are *interlaced* with one another; and the interlacing is performed by means of a vast number of fibres, or teeth, which the laminæ shoot forth *on each side*, and which hook and grapple together. A friend of mine counted fifty of these fibres in one twentieth of an inch. These fibres are crooked, but curved after a different manner: for those, which proceed from the thread on the side towards the extremity of the feather, are longer, more flexible, and bent downward; whereas those which proceed from the side towards the beginning, or quill-end of the feather, are shorter, firmer, and turn upwards. The process then which takes place is as follows:—when two laminæ are pressed together, so that these long fibres are forced far enough over the short ones, *their* crooked parts fall into the cavity made by the crooked parts of the others; just as the latch

that is fastened to a door enters into the cavity of the catch fixed to the door-post, and there hooking itself, *fastens* the door; for it is properly in this manner, that one thread of a feather is fastened to the other.

This admirable structure of the feather, which it is easy to see with the microscope, succeeds perfectly for the use to which nature has designed it; which use was, not only that the laminæ might be united, but that when one thread or lamina has been separated from another by some external violence, it might be reclasped with sufficient facility and expedition.

In the *ostrich*, this apparatus of crotchetts and fibres, of hooks and teeth, is in great measure wanting, and we see the consequence of the want. The filaments hang loose and separate from one another, forming only a kind of down, which constitution of the feathers, however it may fit them for the flowing honours of a lady's head-dress, might be reckoned an imperfection in the bird, if required for flying, inasmuch as wings, composed of these feathers, although they may greatly assist it in running, do not serve for flight.

But under the present division of our sub-

ject, our business with feathers is, as they are the *covering* of the bird. And herein a singular circumstance occurs. In the small order of birds which winter with us, from a snipe downwards, their Creator has universally given them a bed of soft down next their bodies. Down retains air, which is a bad conductor of heat, and the purpose here is to *keep in* the heat, arising from the general circulation of the blood. It is further, likewise, remarkable, that this is not found so abundantly in larger birds; for which there is also a reason:—small birds are much more exposed to the cold than large ones; forasmuch as they present, in proportion to their bulk, a much larger surface to the air. If a turkey were divided into a number of wrens (supposing the shape of the turkey and the wren to be similar), the surface of all the wrens would exceed the surface of the turkey, in the proportion of the length, breadth (or, of any homologous line), of a turkey to that of a wren; which would be, perhaps, a proportion of ten to one. It was necessary, therefore, that small birds should be more warmly clad than large ones; and this seems to be the expedient, by which that exigency is provided for.

II. In comparing different animals, I know no part of their structure which exhibits greater

variety, or, in that variety, a nicer accommodation to their respective conveniency, than that which is seen in the different formations of their *mouths*. Whether the purpose be the reception of aliment merely, or the catching of prey, the picking up of seeds, the cropping of herbage, the extraction of juices, the suction of liquids, the breaking and grinding of food, the taste of that food, together with the respiration of air, and, in conjunction with it, the utterance of sound ; these various offices are assigned to this one part, and, in different species, provided for, as they are wanted, by its different constitution. In the human species, forasmuch as there are hands to convey the food to the mouth, the mouth is flat, and by reason of its flatness, fitted only for *reception* ; whereas the projecting jaws, the wide rictus, the pointed teeth of the dog and his affinities, enable them to apply their mouths to *snatch and seize* the objects of their pursuit. The full lips, the rough tongue, the corrugated cartilaginous palate, the broad cutting teeth of the ox, the deer, the horse, and the sheep, qualify this tribe for *browsing* upon their pasture ; either gathering large mouthfuls at once, where the grass is long, which is the case with the ox in particular ; or biting close where it is short, which

the horse and the sheep are able to do, in a degree that one could hardly expect. The retired under-jaw of a swine *works in the ground*, after the protruding snout, like a prong or plough-share, has made its way to the roots, upon which it feeds. A conformation so happy was not the gift of chance.

The structure of the teeth, as well as their

TOOTH OF RODENT.

Tooth of Porcupine; showing the mode of growth of the incisor teeth of rodents. At the root of the ivory is a vascular pulp (*p*)

relations to each other and their form, is specially adapted to the habits and requirements of animals. Thus, the fangs or *canine* teeth are long, pointed, and strong, to enable the flesh-feeders to seize their prey; whilst the molar or back teeth shut one set within the other, so as to cut or lacerate their food, which is swallowed in large morsels. In the grass-feeders the incisor, or front cutting teeth, are large and

wide, to enable their owners to crop the herbage; but the back teeth are broad, that they may grind their food as in a mill. In another class, the rodents, as the rat, squirrel, and beaver, the front teeth, or incisors, are long and chisel-shaped, for gnawing, and these are kept sharp, and continue to grow as they are worn away.

The arrangement existing for this purpose is remarkable, and too striking to pass by without notice. Besides the pulp which forms the ivory or bone of the tooth, there is a membrane which is designed to produce the hard enamel. But this exists only on the front surface of the socket, and therefore it is only this edge of the tooth that is coated with this structure. Thus, by friction against hard substances, the soft ivory is worn away more rapidly than the dense enamel, and the sharp edge is preserved. If the opposing tooth be lost or broken, that which is left continues to grow to an inordinate length. This beautiful adaptation to the habits of the animal is well exemplified in the porcupine.

In other instances, likewise, the structure of teeth varies according to their uses. Thus, in rodents, the cutting teeth are composed chiefly of ivory, because it is necessary they should

wear away with regularity as they continue to grow from the sockets. In flesh-feeders, including man, the bony part of the tooth is covered, beyond the gum, with a coating of

ELEPHANT'S TOOTH.

Elephant's grinder, showing its component structures. A, seen from above. B, in section. The dentine papillæ (*d*) are enclosed in enamel (*e*), and the cement (*c*) is interposed between adjoining layers of enamel.

very hard and white enamel; these teeth are permanent, and do not grow after attaining their full size. But the mill-stone, grinding teeth of herbivorous animals, though broad on their surface, are irregular, presenting prominences and deep grooves, which are *not* worn

flat by their grinding use. This important result is secured by the alternation of the enamel and ivory in their relation to each other in the construction of the tooth; and these textures are moreover imbedded in a third, called the cement, as in the Elephant's grinders. Now, as each of these textures is of a different degree of hardness, they wear away unequally, and thus the permanent irregularity of the surface is provided for.

In man, who is a mixed feeder, the type of the animal and vegetable-feeder is combined.

In *birds*, the mouth assumes a new character; new both in substance and in form; but in both, wonderfully adapted to the wants and uses of a distinct mode of existence. We have no longer the fleshy lips, the teeth of enamelled bone; but we have, in the place of these two parts, and to perform the office of both, a hard substance (of the same nature with that which composes the nails, claws, and hoofs of quadrupeds) cut out into proper shapes, and mechanically suited to the actions which are wanted. The sharp edge and tempered point of the *sparrow's* bill picks almost every kind of seed from its concealment in the plant; and not only so, but hulls the grain, breaks and shatters the coats of the seed, in order to get at the

---

kernel. The hooked beak of the hawk-tribe separates the flesh from the bones of the animals which it feeds upon, almost with the cleanliness and precision of a dissector's knife. The butcher-bird transfixes its prey upon the spike of a thorn, whilst it picks its bones. In some birds of this class, we have the *cross-bill*, i. e., both the upper and lower bill hooked, and their tips crossing. The *spoon-bill* enables the goose to graze, to collect its food from the bottom of pools, or to seek it amidst the soft or liquid substances with which it is mixed. The *long*, tapering bill of the snipe and woodcock penetrates still deeper into moist earth, which is the bed in which the food of that species is lodged. This is exactly the instrument which the animal wanted. It did not want strength in its bill, which was inconsistent with the slender form of the animal's neck, as well as unnecessary for the kind of aliment upon which it subsists; but it wanted length to reach its object.

But the species of bill which belongs to birds that live by *suction*, deserves to be described in its relation to that office. They are what naturalists call serrated or dentated bills; the inside of them, towards the edge, being thickly set with parallel or concentric rows of short,

strong, sharp-pointed prickles. These, though they should be called teeth, are not for the purpose of mastication, like the teeth of quadrupeds ; nor yet, as in fish, for the seizing and retaining of their prey ; but for a quite different use. They form a filter. The *duck* by means of them discusses the mud ; examining with great accuracy the puddle, the brake, every mixture which is likely to contain her food. The operation is thus carried on :—The liquid or semi-liquid substances, in which the animal has plunged her bill, she draws, by the action of her lungs, through the narrow interstices which lie between these teeth ; catching, as the stream passes across her beak, whatever it may happen to bring along with it, that proves agreeable to her choice, and easily dismissing all the rest. Now, suppose the purpose to have been, out of a mass of confused and heterogeneous substances; to separate for the use of the animal, or rather to enable the animal to separate for its own, those few particles which suited its taste and digestion ; what more artificial, or more commodious instrument of selection, could have been given to it, than this natural filter ? It has been observed, also (what must enable the bird to choose and distinguish with greater acuteness, as well,

probably, as what greatly increases its luxury), that the bills of this species are furnished with large nerves,—that they are covered with a skin,—and that the nerves run down to the very extremity. In the curlew, woodcock, and snipe, there are *three pairs* of nerves, equal almost to the optic nerve in thickness, which pass first along the roof of the mouth, and then along the upper chap down to the point of the bill, long as the bill is.

But to return to the train of our observations.—The similitude between the bills of birds, and the mouths of quadrupeds, is exactly such, as, for the sake of the argument, might be wished for. It is near enough to show the continuation of the same plan; it is remote enough to exclude the supposition of the difference being produced by action or use. A more prominent contour, or a wider gape, might be resolved into the effect of continued efforts, on the part of the species, to thrust out the mouth, or open it to the stretch. But by what course of action, or exercise, or endeavour, shall we get rid of the lips, the gums, the teeth; and acquire, in the place of them, pincers of horn? By what habit shall we so completely change, not only the shape of the part, but the substance of which it is com-

posed? The truth is, if we had seen no other than the mouths of quadrupeds, we should have thought no other could have been formed: little could we have supposed, that all the purposes of a mouth, furnished with lips, and armed with teeth, could be answered by an instrument which had none of these; could be supplied, and that with many additional advantages, by the hardness, and sharpness, and figure of the bills of birds. Everything about the animal *mouth* is mechanical. The teeth of fish have their points turned backwards, like the teeth of a wool or cotton card. The teeth of lobsters work one against another, like the sides of a pair of shears. In many insects, the mouth is converted into a pump or sucker, fitted at the end sometimes with a wimble, sometimes with a forceps; by which double provision, viz. of the tube and the penetrating form of the point, the insect first bores through the integuments of its prey and then extracts the juices. And, what is most extraordinary of all, one sort of mouth, as the occasion requires, shall be changed into another sort. The caterpillar could not live without teeth; in several species, the butterfly formed from it could not use them. The old teeth, therefore, are cast off with the exuviae of the grub; a

new and totally different apparatus assumes their place in the fly. Amid these novelties of form, we sometimes forget that it is, all the while, the animal's *mouth*; that, whether it be lips, or teeth, or bill, or beak, or shears, or pump, it is the same part diversified; and it is also remarkable, that, under all the varieties of configuration with which we are acquainted, and which are very great, the organs of taste and smelling are situated near each other.

III. To the mouth adjoins the gullet: in this part, also, comparative anatomy discovers a difference of structure, adapted to the different necessities of the animal. In brutes, because the posture of their neck conduces little to the passage of the aliment, the fibres of the gullet, which act in this business, run in two close spiral lines, crossing each other: in men, these fibres run in two layers, longitudinal and circular, from the upper end of the œsophagus to the stomach, into which, by a gentle contraction, they easily transmit the descending morsels; that is to say, for the more laborious deglutition of animals, which thrust their food *up* instead of *down*, and also through a longer passage, a proportionably more powerful apparatus of muscles is provided; more powerful, not merely by the strength of the fibres, which

might be attributed to the greater exercise of their force, but in their collocation, which is a determinate circumstance, and must have been original.

The gullet leads to the stomach, which is an expanded chamber, single in most mammals, and presenting a tolerably uniform structure: it is here that the earliest and most important stage of digestion takes place. But ruminants, or those animals which chew the cud, possess a compound stomach consisting of four cavities, which present important differences in their size and structure. The first is very large, and receives the crude, unmasticated food, as it is gathered and accumulated by the feeder. The second is much smaller, and has a honey-comb appearance on its interior. The third has its lining membrane thrown into longitudinal folds, so as to present a very extended surface. The fourth cavity, which opens into the intestine, also presents a folded appearance, and is similar in texture and function to the single stomach of other mammals. The œsophagus communicates with both the paunch, or large receptacle, and the other cavities. When sufficient food is collected, and the cud is to be chewed, a small mass of it is admitted into the second stomach, and thence carried up-

wards by the strong spiral muscles of the œsophagus into the mouth. After thorough mastication it is again swallowed, and admitted into the third cavity, from which it passes into the true stomach for digestion. The arrangements for this alteration of the course of the food according to circumstances are strictly mechanical, though governed by the requirements of the time. It is an interesting circumstance to notice that, in the young sucking ruminant, the first three cavities are comparatively undeveloped, and the milk passes directly to the true stomach for digestion.

The different length of the intestines in carnivorous and herbivorous animals has been noticed on a former occasion. The shortest, I believe, is that of some birds of prey, in which the intestinal canal is little more than a straight passage from the mouth to the vent. The longest is in the deer kind. The intestines of a Canadian stag, four feet high, measured ninety-six feet<sup>1</sup>. The intestine of a sheep, unravelled, measured thirty times the length of the body. The intestine of a wild cat is only three times the length of the body. Universally, where the substance upon which the

<sup>1</sup> Mem. Acad. Paris, 1701, p. 170.

animal feeds is of slow concoction, and less closely allied with the animal fabric into which it has to be converted, there the passage is circuitous and dilatory, that time and space may be allowed for the change and the absorption which are necessary. Where the food is soon dissolved, or already half assimilated, an unnecessary, or perhaps hurtful, detention is avoided by giving to it a shorter and a readier route.

V. In comparing the *bones* of different animals, we are struck, in the bones of birds, with a *propriety*, which could only proceed from the wisdom of an intelligent and designing Creator. In the bones of an animal which is to fly, the two qualities required are strength and lightness. Wherein, therefore, do the bones of birds (I speak of the cylindrical bones) differ in these respects from the bones of quadrupeds? In three properties: first, their cavities are much larger in proportion to the weight of the bone than in those of quadrupeds; secondly, these cavities are occupied by air at a high temperature; thirdly, the shell is of a firmer texture than the substance of other bones. It is easy to observe these particulars, even in picking the wing or leg of a chicken. Now, the weight being the same, the diameter, it is

---

evident, will be greater in a hollow bone than in a solid one, and with the diameter, as every mathematician can prove, is increased, *cæteris paribus*, the strength of the cylinder, or its resistance to breaking. In a word, a bone of the *same weight* would not have been so strong in any other form ; and to have made it heavier, would have incommoded the animal's flight. Yet this form could not be acquired by use, or the bone become hollow and tubular by exercise. What appetency could excavate a bone ?

VI. The *lungs* also of birds, as compared with the lungs of quadrupeds, contain in them a provision, especially calculated for this same purpose of levitation ; namely, a communication (not found in other kinds of animals) between the air-vessels of the lungs and the cavities of the body, as well as the bones ; so that by the intromission of air from one to the other (at the will, as it should seem, of the animal), its body can be occasionally puffed out, and its tendency to descend in the air, or its specific gravity, made less. The bodies of birds are blown up from their lungs (which no other animal bodies are), and thus rendered buoyant. Moreover, by this peculiar arrangement, the blood throughout the body is more generally

and constantly supplied with oxygen, than where the interchange of gases takes place in the lungs alone; whilst the high temperature of the breathed air rarifies it, and the whole bird is thus rendered relatively lighter in the cooler atmosphere through which it moves.

VII. All birds are *oviparous*. This likewise carries on the work of gestation with as little increase as possible of the weight of the body. A gravid uterus would have been a troublesome burthen to a bird in its flight. The advantage in this respect of an oviparous procreation is, that, whilst the whole brood are hatched together, the eggs are excluded singly, and at considerable intervals. Ten, fifteen, or twenty young birds may be produced in one cletch or covey, yet the parent bird may have never been encumbered by the load of more than one full-grown egg at one time.

VIII. A principal topic of comparison between animals is in their *instruments of motion*. These come before us under three divisions; feet, wings, and fins. I desire any man to say, which of the three is best fitted for its use; or whether the same consummate art be not conspicuous in them all. The constitution of the elements, in which the motion is to be performed, is very different. The animal action

must necessarily follow that constitution. The Creator, therefore, if we might so speak, had to prepare for different situations, for different difficulties ; yet the purpose is accomplished not less successfully in one case than in the other. And, as between *wings* and the corresponding limbs of quadrupeds, it is accomplished without deserting the general idea. The idea is modified, not deserted. Strip a wing of its feathers, and it bears no obscure resemblance to the foreleg of a quadruped. The articulations at the shoulder and the arm are much alike ; and, what is a closer circumstance, in both cases the upper part of the limb consists of a single bone, the lower part of two.

But, fitted up with its furniture of feathers and quills, it becomes a wonderful instrument, more artificial than its first appearance indicates, though that be very striking : at least, the use which the bird makes of its wings in flying is more complicated, and more curious, than is generally known. One thing is certain, that if the flapping of the wings in flight were no more than the reciprocal motion of the same surface in opposite directions, either upwards and downwards, or estimated in any oblique line, the bird would lose as much by one motion as she gained by another. The skylark

could never ascend by such an action as this; for, though the stroke upon the air by the under side of her wing would carry her up, the stroke from the upper side, when she raised her wing again, would bring her down. In order, therefore, to account for the advantage which the bird derives from her wing, it is necessary to suppose that the surface of the wing, measured upon the same plane, is contracted whilst the wing is drawn up; and let out to its full expansion, when it descends upon the air for the purpose of moving the body by the reaction of that element. Now, the form and structure of the wing, its external convexity, the disposition, and particularly the overlapping of its larger feathers, the action of the muscles, and joints of the pinions, are all adapted to this alternate adjustment of its shape and dimensions. Such a twist, for instance, or semi-rotatory motion, is given to the great feathers of the wing, that they strike the air with their flat side, but rise from the stroke slantwise. The turning of the oar in rowing, whilst the rower advances his hand for a new stroke, is a similar operation to that of the feather, and takes its name from the resemblance. I believe that this faculty is not found in the great feathers of the tail. This is the

place also for observing that the pinions are so set upon the body as to bring down the wings, not vertically, but in a direction obliquely tending towards the tail; which motion, by virtue of the common resolution of forces, does two things at the same time; supports the body in the air, and carries it forward. The *steerage* of a bird in its flight is effected partly by the wings, but in a principal degree by the tail. And herein we meet with a circumstance not a little remarkable. Birds with long legs have short tails, and in their flight place their legs close to their bodies, at the same time stretching them out backwards as far as they can. In this position the legs extend beyond the rump, and become the rudder, supplying that steerage which the tail could not.

From the *wings* of birds, the transition is easy to the *fins* of fish. They are both, to their respective tribes, the instruments of their motion; but in the work which they have to do there is a considerable difference, founded in this circumstance. Fish, unlike birds, have very nearly the same specific gravity as the element in which they move. In the case of fish, therefore, there is little or no weight to bear up; what is wanted is only an impulse sufficient to carry the body through a resisting

medium, or to maintain the posture, or to support or restore the balance of the body, which is always the most unsteady where there is no weight to sink it. For these offices the fins are as large as necessary, though much smaller than wings, their action mechanical, their position, and the muscles by which they are moved, in the highest degree convenient. The following short account of some experiments upon fish, made for the purpose of ascertaining the use of their fins, will be the best confirmation of what we assert. In most fish, beside the great fin the tail, we find two pairs of fins upon the sides, two single fins upon the back, and one upon the belly, or rather, between the belly and the tail. The *balancing* use of these organs is proved in this manner. Of the large-headed fish, if you cut off the pectoral fins, i. e. the pair which lies close behind the gills, the head falls prone to the bottom; if the right pectoral fin only be cut off, the fish leans to that side; if the ventral fin on the same side be cut away, then it loses its equilibrium entirely; if the dorsal and ventral fins be cut off, the fish reels to the right and left. The use of the same parts for *motion* is seen in the following observation upon them when put in action. The pectoral, and more particularly

---

the ventral fins, serve to *raise and depress* the fish : when the fish desires to have a *retrograde* motion, a stroke forward with the pectoral fin effectually produces it ; if the fish desire to *turn* either way, a single blow with the tail the opposite way sends it round at once ; if the tail strike both ways, the motion produced by the double lash is *progressive*, and enables the fish to dart forwards with an astonishing velocity. The result is not only in some cases the most rapid, but in all cases the most gentle, pliant, easy animal motion, with which we are acquainted. However, when the tail is cut off, the fish loses all motion, and gives itself up to where the water impels it. The rest of the fins, therefore, so far as respects motion, seem to be merely subsidiary to this. In their mechanical use, the anal fin may be reckoned the keel ; the ventral fins, out-riggers ; the pectoral muscles, the oars ; and if there be any similitude between these parts of a boat and a fish, observe, that it is not the resemblance of imitation, but the likeness which arises from applying similar mechanical means to the same purpose.

We have seen that the *tail* in the fish is the great instrument of motion. Now, in cetaceous or warm-blooded fish, which are obliged to

rise every two or three minutes to the surface to take breath, the tail, unlike what it is in other fish, is horizontal; its stroke consequently perpendicular to the horizon, which is the right direction for sending the fish to the top or carrying it down to the bottom.

Regarding animals in their instruments of motion, we have only followed the comparison

FEET OF BIRDS.

Birds' feet, to show the contrast between the walking and the swimming birds.

through the first great division of animals into beasts, birds, and fish. If it were our intention to pursue the consideration further, I should take in that generic distinction amongst birds, the *web-foot* of water-fowl. It is an instance which may be pointed out to a child. The utility of the web to water-fowl, the inutility to land-fowl are so obvious, that it seems impossible to notice the difference with-

---

out acknowledging the design. I am at a loss to know, how those who deny the agency of an intelligent Creator dispose of this example. There is nothing in the action of swimming, as carried on by a bird upon the surface of the water, that should generate a membrane between the toes. As to that membrane, it is an exercise of constant resistance. The only supposition I can think of is, that all birds have been originally water-fowl and web-footed; that sparrows, hawks, linnets, &c. which frequent the land, have in process of time, and in the course of many generations, had this part worn away by treading upon hard ground. To such evasive assumptions must atheism always have recourse! and after all, it confesses that the structure of the feet of birds, in their original form, was critically adapted to their original destination! The web-feet of amphibious quadrupeds, seals, otters, &c. fall under the same observation.

IX. The *five senses* are common to most large animals; nor have we much difference to remark in their constitution; or much, however, which is referable to mechanism.

The superior sagacity of animals which hunt their prey, and which consequently depend for their livelihood upon their *nose*, is well

known in its use ; and this is dependent, for its degree of perfection, on the complicated arrangement of the bones within the nose, the

HEAD OF A TIGER,

To show the forward direction of the ears in those animals which *pursue* others for prey.

corresponding extent of the delicate membrane which covers them, and the size of the olfactory nerves which are distributed to them.

The nostrils of the whale tribe present a

remarkable deviation from the type these parts present in other mammals: they are, in fact, not olfactory organs at all, for this sense is not

HEAD OF AN ANTELOPE,

To show the backward direction of the ears in those animals which are *pursued*, for prey, by others.

needed by these inhabitants of the sea, which nevertheless breathe atmospheric air. The nostrils, therefore, are used as breathing holes alone, and are placed on the top of the head,

to enable the animal to respire as soon as it reaches the surface of the water: and for this purpose, these apertures communicate by canals with the air-tube, without entering the mouth. Yet, by a complex valvular apparatus, the water may be ejected from the mouth through these canals and *blow-holes*, as they are termed, at the summit of the head.

The external *ears* of beasts of prey, of lions, tigers, wolves, have their trumpet part, or concavity, standing forwards, to seize the sounds which are before them, viz. the sounds of the animals which they pursue or watch. The ears of animals of flight are turned backward, to give notice of the approach of their enemy from behind, whence he may steal upon them unseen. This is a critical distinction, and is mechanical: but it may be suggested, and I think not without probability, that it is the effect of continual habit.

There appears to be also in the figure, and in some properties of the pupil of the eye, an appropriate relation to the wants of different animals. In the smaller animals of the cat tribe, which hunt by night, the pupil is a long, vertical fissure, admitting of large dilatation, to catch every ray of light. In horses, oxen, goats, sheep, the pupil of the eye is

elliptical ; the transverse axis being horizontal ; by which structure, although the eye be placed on the side of the head, the anterior elongation of the pupil catches the forward rays, or those which come from objects immediately in front of the animal's face.

## CHAPTER XIII.

## PECULIAR ORGANIZATIONS.

I BELIEVE that all the instances which I shall collect under this title, might, consistently enough with technical language, have been placed under the head of *Comparative Anatomy*. But the purpose of this chapter is to direct attention to some instances of special organization, which cannot be aptly compared with any similar structures in other animals. Of this kind are the examples which I have to propose: and the reader will see that, though some of them be the strongest, perhaps, he will meet with under any division of our subject, they must necessarily be of an unconnected and miscellaneous nature. To dispose them, however, into some sort of order, we will notice, first, particularities of structure which belong to quadrupeds, birds, and fish, as such, or to many of the kinds included in these classes of animals;

and then, such particularities as are confined to one or two species.

I. In many animals, such as those which browse on the ground, with heavy heads and horns, as the horse or stag, or with long necks, as the giraffe and camel, there must necessarily

SKELETON OF A LION,

Showing the spinous processes of the vertebræ, to which the elastic ligament supporting the head is attached.

be a large expenditure of muscular force to raise the head, and even to keep it erect, if there were not some compensating arrangement to afford the requisite support. This is accomplished by the presence of a broad, powerful band, or rather sheet of elastic texture, which

extends from the back of the skull along the spines of the cervical vertebræ, or even further backwards; and thus the muscular force is economized, by the head being supported by this suspensory ligament; and grace and ease in movement are substituted for awkward and painful exertion.

II. The structure which is known as whalebone really occupies the position, though it cannot be said to perform the office, of teeth. It consists in the whale of several rows of flat plates, of which the outer are the longest, attached to the gums of the upper jaw. These plates are arranged in parallel order, many being of great length, and terminating, at their free border, in a horny fringe, resembling coarse hair. Through this enormous sieve the water which is taken into the mouth is strained ; and the molluscs, which form the food of this huge animal, are thus gathered for its use. As this whalebone wears away, it is constantly replaced by fresh growth from below. It would be difficult to point out a more remarkable and unique adaptation to a particular purpose, than is presented by this singular development in place of teeth.

III. The oil with which *birds* prune their feathers, and the organ which supplies it, is a specific provision for the winged creation. On

each side of the rump of birds is observed a small nipple, yielding upon pressure a butter-like substance, which the bird extracts by pinching the pap with its bill. With this oil, or ointment, thus procured, the bird dresses its coat; and repeats the action as often as its own sensations teach it that it is in any part wanted, or as the excretion may be sufficient for the expense. The value of this arrangement, in water-fowl especially, must be apparent; as they are thereby enabled to keep their plumage dry. The gland, the pap, the nature and quality of the excreted substance, the manner of obtaining it from its lodgment in the body, the application of it when obtained, form, collectively, an evidence of intention which it is not easy to withstand. Nothing similar to it is found in unfeathered animals. What blind *conatus* of nature should produce it in birds; should not produce it in beasts?

IV. The swimming-bladder of a fish is a bag containing air, fixed firmly beneath the spine, and varying considerably in its shape. It is strong in its structure, and from it isin-glass is obtained. The air is produced, as a secretion, from the inner surface of the bladder, which, in some instances, is a closed sac, but in others communicates with the œsophagus or

stomach. The voluntary muscular compression

THE FAHAKA OF THE NILE,  
Opened to show the air-bladder.

of this bag is effected by the contraction of the

walls of the abdomen, or by a special muscular apparatus provided in some fishes.

This air-bladder therefore affords a plain and direct instance, not only of contrivance, but strictly of that species of contrivance which we denominate mechanical. It is a philosophical apparatus in the body of an animal. The principle of the contrivance is clear; the application of the principle is also clear. The use of the organ to sustain, and, at will, also to elevate the body of the fish in water, is proved by observing, what has been tried, that when the bladder is burst the fish grovels at the bottom; and also, that flounders, soles, skates, which are without the air-bladder, seldom rise in the water, and that with effort. The manner in which the purpose is attained, and the suitableness of the means to the end, are not difficult to be apprehended. The rising and sinking of a fish in water, so far as it is independent of the stroke of the fins and the tail, can only be regulated by the specific gravity of the body. When the bladder contained in the body of the fish is contracted, which the fish so provided possesses a muscular power of doing, the bulk of the fish is contracted along with it; whereby, since the absolute weight remains the same, the specific gravity, which is the sinking force,

is increased, and the fish descends : on the contrary, when, in consequence of the relaxation of the muscles, the expansion of the previously compressed space restores the dimensions of the bladder, the tendency downwards becomes proportionably less than it was before, or is turned into a contrary tendency. These are known properties of bodies immersed in a fluid. The enamelled figures, or little glass bubbles, in a jar of water, are made to rise and fall by the same artifice. A diving machine might be made to ascend and descend, upon the like principle ; namely, by introducing into the inside of it an air-vessel, which, by its contraction would diminish, and by its distension enlarge, the bulk of the machine itself, and thus render it specifically heavier, or specifically lighter, than the water which surrounds it. Suppose this to be done, and the artist to solicit a patent for his invention. The inspectors of the model, whatever they might think of the use or value of the contrivance, could by no possibility entertain a question in their minds, whether it were a contrivance or not. No reason has ever been assigned,—no reason can be assigned, why the conclusion is not as certain in the fish as it is in the machine; why the argument is not as firm in one case as the other.

Nothing similar to the air-bladder is found in land-animals; and a life in the water has no natural tendency to produce a bag of air. Nothing can be further from an acquired organization than this is.

HEAD OF A RATTLE-SNAKE,

Partially dissected, to show the fangs and the poison-bag.

These examples mark the attention of the Creator to the three great kingdoms of His animal creation,—and to their constitution as such. The example which stands next in point of generality, belonging to a large tribe of animals, or rather to various species of a tribe, is the poisonous tooth of serpents.

I. The poison fangs of venomous snakes present a clear and striking example of special mechanical contrivance. These teeth, two in number, are fixed in the front of the upper jaw, and are long and pointed. Each tooth is traversed by a canal, which has a large triangular opening near the base of the tooth, and terminates, near the point, in a narrow fissure. Further, these peculiar teeth are usually hidden in the roof of the mouth, where they lie flat, covered by a fold of the mucous membrane ; but the animal has the power of erecting them suddenly by the action of muscles appropriated to that special purpose. But why does all this peculiar mechanism exist? It is explained by the presence of a large gland which secretes a deadly poison, and which is so enveloped in the muscular apparatus by which the jaws are closed, that during that movement the poison is forcibly injected into the canal in the tooth, along which it finds its way into the pierced body of the victim. The permanent erection of these teeth would be a palpable and serious inconvenience to the animal, and therefore they are usually hidden. If a poison fang be broken off, another is developed to take its place and perform its office. What more unequivocal or effectual apparatus could be devised, for the

---

double purpose of at once inflicting the wound and injecting the poison ?

II. In being the property of several different species, the preceding example is resembled by that which I shall next mention, which is the *bag of the opossum*. This is a mechanical contrivance, most properly so called ; and is specially needed in this singular class of animals, in which the young are born at so early a period of their development, and require to be constantly in close relation with the source of their nutriment. The simplicity of the expedient renders the contrivance more obvious than many others, and by no means less certain. The skin under the belly of the animal forms a pouch, into which the young litter are received at their birth ; where they have an easy and constant access to the teats ; in which they are transported by the dam from place to place ; where they are at liberty, when sufficiently strong, to run in and out ; and where they find a refuge from surprise and danger. It is their cradle, their asylum, and the machine for their conveyance. Can the use of this structure be doubted of ? Nor is it a mere doubling of the skin ; it is a special organ, furnished with a pair of bones for its support, which are attached to the front of the os pubis ;

and the mouth of this sac is closed by a strong cutaneous sphincter muscle. Whilst the young are too feeble to suck, the milk is pressed from the teat into the clinging mouth of the foetus by a special muscular arrangement; and the relation between the wind-pipe and oesophagus is peculiarly adapted to obviate the risk of suffocation, in swallowing, at this period of the animal's existence.

III. As a particularity, yet appertaining to more species than one, and also as strictly mechanical, we may notice a circumstance in the structure of the *claws* of certain birds. The middle claw of the heron and cormorant is toothed and notched like a saw. These birds are great fishers, and these notches assist them in holding their slippery prey. The use is evident; but the structure is such as cannot at all be accounted for by the effort of the animal, or the exercise of the part. Some other fishing birds have these notches in their *bills*; and for the same purpose. The gannet, or Soland goose, has the side of its bill irregularly jagged, that it may hold its prey the faster. Nor can the structure in this, more than in the former case, arise from the manner of employing the part. The smooth surfaces, and soft flesh of fish, were less likely to notch

the bills of birds, than the hard bodies upon which many other species feed.

We now come to particularities strictly so called, as being limited to a single species of animal. Of these I shall take one from a quadruped and one from a bird.

I. The *stomach* of the camel is well known to retain large quantities of water, and to retain it unchanged for a considerable length of time. This property qualifies it for living in the desert. Let us see, therefore, what is the internal organization, upon which a faculty so rare, and so beneficial depends. A number of distinct cells or bags (in a dromedary thirty of these have been counted) are observed to lie between the membranes of the second stomach and part of the paunch, and to open into the stomach near the top by small square apertures. Through these orifices, after the stomach is full, the annexed bags are filled from it; and the water so deposited is retained there by the muscular contraction of the orifice of each cell, and is therefore not liable to pass into the intestines; in the second place, it is kept separate from the solid aliment; and, in the third place, it is out of the reach of the digestive action of the stomach, or of mixture with the gastric juice. It appears probable, or rather certain,

that the animal, by the conformation of its muscles, possesses the power of squeezing back this water from the adjacent bags into the stomach, whenever thirst excites it to put this power in action.

SKULL OF A WOODPECKER,

Showing the remarkably long and elastic tongue, which is attached to the *upper* part of the head.

II. The *tongue of the woodpecker* is one of those singularities which nature presents us with, when a single purpose is to be answered. It is a particular instrument for a particular use: and what, except design, ever produces such? The woodpecker lives chiefly upon insects, lodged in the bodies of decayed or decaying trees. For the purpose of boring into the wood, it is furnished with a bill, straight, hard, angular, and sharp. When, by means of this piercer, it has reached the cells of the insects, then comes the office of its tongue; which tongue is, first,

of such a length that the bird can dart it out three or four inches from the bill,—in this respect differing greatly from every other species of bird; in the second place, it is tipped with a stiff, sharp, bony thorn; and, in the third place (which appears to me the most remarkable property of all), this tip is dentated on both sides, like the beard of an arrow or the barb of a hook. The description of the part declares its uses. The bird, having exposed the retreats of the insects by the assistance of its bill, with a motion inconceivably quick, launches out at them this long tongue, transfixes them upon the barbed needle at the end of it, and thus draws its prey within its mouth. If this be not mechanism, what is? Should it be said that, by continual endeavours to shoot out the tongue to the stretch, the woodpecker's species may by degrees have lengthened the organ itself, beyond that of other birds, what account can be given of its form, of its tip? how, in particular, did it get its barb, its dentation? These barbs, in my opinion, wherever they occur, are decisive proofs of mechanical contrivance.

To the foregoing instances may be added another,—

III. The walrus, a gigantic seal, is provided with two canine teeth in the upper jaw, of great

size and strength, and attaining from one to two feet in length. The habits of the animal are inconsistent with the use of these tusks as ordinary weapons of offence; but they are employed as climbing instruments, by which the animal drags its heavy body along the ground, or clings to the rock whilst reposing in the water.

The habits of the sloth were unknown long after we were acquainted with the animal, which was regarded by eminent naturalists as affording an exemplification of awkward and unmeaning construction. (Cuvier speaks of nature having “wished to produce something imperfect and grotesque.”) Its fingers are connected together, and armed with enormous hooked claws. Its hind feet are so joined to the legs as to rest only on their outer borders, and the front limbs are much longer than the hind. The consequence of these peculiarities is that the animal moves along the ground with a painful and awkward slowness. But, when seen hanging securely from branches of trees on which it feeds, the explanation of this peculiar organization becomes apparent, and its strength and activity are quite equal to its necessities in moving from branch to branch, in clinging, or in swinging itself from tree to tree.

## CHAPTER XIV.

## PROSPECTIVE CONTRIVANCES.

I CAN hardly imagine to myself a more distinguished mark, and consequently a more certain proof, of design, than *preparation*, i. e. the providing of things beforehand which are not to be used until a considerable time afterwards; for this implies a contemplation of the future, which belongs only to intelligence.

Of these *prospective* contrivances, the bodies of animals furnish various examples.

I. The human teeth afford an instance, not only of prospective contrivance, but of the completion of the contrivance being designedly suspended. They are formed within the gums, and there they stop; the fact being, that their further advance to maturity would not only be useless to the new-born animal, but extremely in its way; as it is evident that the act of *sucking*, by which it is for some time to be

nourished, will be performed with more ease both to the nurse and to the infant, whilst the inside of the mouth and edges of the gums are smooth and soft, than if set with hard pointed bones. By the time they are wanted, the teeth are ready. They have been lodged within the gums for some months past, but detained, as it were in their sockets, so long as their further protrusion would interfere with the office to which the mouth is destined. Nature, namely, that intelligence which was employed in creation, looked beyond the first year of the infant's life; yet, whilst she was providing for functions which were after that term to become necessary, was careful not to incommod those which preceded them. What renders it more probable that this is the effect of design, is, that the teeth are imperfect, whilst all other parts of the mouth are perfect. The lips are perfect, the tongue is perfect; the cheeks, the jaws, the palate, the pharynx, the larynx, are all perfect; the teeth alone are not so. This is the fact with respect to the human mouth: the fact also is that the parts above enumerated are called into use from the beginning, whereas the teeth would be only so many obstacles and annoyances, if they were there. When a contrary order is necessary,

---

a contrary order prevails. In the worm of the beetle, as hatched from the egg, the teeth are the first things which arrive at perfection. The insect begins to gnaw as soon as it escapes from the shell, though its other parts be only gradually advancing to their maturity.

What has been observed of the teeth is true of the *horns* of animals, and for the same reason. The horn of a calf or a lamb does not bud, or at least does not sprout to any considerable length, until the animal be capable of browsing upon its pasture ; because such a substance upon the forehead of the young animal would very much incommod the teat of the dam in the office of giving suck.

But in the case of the *teeth*,—of the human teeth at least,—the prospective contrivance looks still further. A succession of crops is provided, and provided from the beginning ; a second tier being originally formed beneath the first, which do not come into use till several years afterwards. And this double or suppletory provision meets a difficulty in the mechanism of the mouth, which would have appeared almost insurmountable. The expansion of the jaw (the consequence of the proportionable growth of the animal, and of its skull,) necessarily

separates the teeth of the first set, however compactly disposed, to a distance from one another which would be very inconvenient. In due time, therefore, i. e. when the jaw has attained a great part of its dimensions, a new set of teeth springs up, larger and more numerous, more exactly fitted to the space which they are to occupy, and rising also in such close ranks, as to allow for any extension of line which the subsequent enlargement of the head may occasion. This new growth is preceded by the loosening of the first set, which are cast out to make way for the permanent teeth.

II. It is not very easy to conceive a more evidently prospective contrivance than that which, in all viviparous animals, is found in the *milk* of the female parent. At the moment the young animal enters the world, there is its maintenance ready for it. The particulars to be remarked in this economy are neither few nor slight. We have first the nutritious quality of the fluid, unlike, in this respect, every other excretion of the body; and in which nature hitherto remains unimitated, neither cookery nor chemistry having been able to make milk out of grass; we have, secondly, the organ for its production, existing only in the female; we have, thirdly, the excretory duct

---

annexed to that organ; and we have, lastly, the determination of the milk to the breast, at the particular juncture when it is about to be wanted. We have all these properties in the subject before us; and they are all indications of design. The last circumstance is the strongest of any. If I had been to guess beforehand, I should have conjectured, that at the time when there was an extraordinary demand for nourishment in one part of the system there would be the least likelihood of a redundancy to supply another part. The advanced pregnancy of the female has no intelligible tendency to fill the breast with milk. The lacteal system is a constant wonder; and it adds to other causes of our admiration, that the number of the teats or paps in each species is found to bear a proportion to the number of the young. In the sow, the bitch, the rabbit, the cat, the rat, which have numerous litters, the paps are numerous, and are disposed along the whole length of the belly; in the cow and mare, they are few. The most simple account of this is to refer it to a designing Creator.

BUT, in the argument before us we are entitled to consider not only animal bodies when framed, but the circumstances under which

they are framed ; and in this view of the subject, the constitution of many of their parts is most strictly prospective.

III. The eye is of no use at the time when it is formed. It is an optical instrument made in a dungeon ; constructed for the refraction of light to a focus, and perfect for its purpose before a ray of light has had access to it ; geometrically adapted to the properties and action of an element with which it has no communication. It is about indeed to enter into that communication ; and this is precisely the thing which evidences intention. It is *providing* for the *future* in the closest sense which can be given to these terms ; for it is providing for a future change, not for the then-subsisting condition of the animal, nor for any gradual progress or advance in that same condition, but for a new state, the consequence of a great and sudden alteration, which the animal is to undergo at its birth. Is it to be believed that the eye was formed, or which is the same thing, that the series of causes was fixed by which the eye is formed, without a view to this change ; without a prospect of that condition, in which its fabric, of no use at present, is about to be of the greatest ; without a consideration of the qualities of that element, hitherto entirely

---

excluded, but with which it was hereafter to hold so intimate a relation? A young man makes a pair of spectacles for himself against he grows old; for which spectacles he has no want or use whatever at the time he makes them. Could this be done without knowing and considering the defect of vision to which advanced age is subject? Would not the precise suitableness of the instrument to its purpose, of the remedy to the defect, of the convex lens to the flattened eye, establish the certainty of the conclusion, that the case, afterwards to arise, had been considered beforehand, speculated upon, provided for? all which are exclusively the acts of a reasoning mind. The eye formed in one state, for use only in another state, and in a different state, affords a proof no less clear of destination to a future purpose, and a proof proportionably stronger, as the machinery is more complicated and the adaptation more exact.

IV. What has been said of the eye holds equally true of the lungs. Composed of air-vessels, where there is no air; elaborately constructed for the alternate admission and expulsion of an elastic fluid, where no such fluid exists; this great organ, with the whole apparatus belonging to it, lies collapsed in the foetal

thorax, yet in order, and in readiness for action, the first moment that the occasion requires its service. This is having a machine locked up in store for future use: which incontestably proves, that the case was expected to occur, in which this use might be experienced: but expectation is the proper act of intelligence. Considering the state in which an animal exists before its birth, I should look for nothing less in its body than a system of lungs. It is like finding a pair of bellows in the bottom of the sea; of no sort of use in the situation in which they are found; formed for an action which was impossible to be exerted; holding no relation or fitness to the element which surrounds them, but both to another element in another place.

As part and parcel of the same plan ought to be mentioned, in speaking of the lungs, the provisional contrivances of the *foramen ovale* and *ductus arteriosus*. In the foetus, pipes are laid for the passage of the blood through the lungs; but, until the lungs be inflated by the inspiration of air, that passage is impervious, or in a great degree obstructed. What then is to be done? what would an artist, what would a master, do upon the occasion? He would endeavour, most probably, to provide a *tempo-*

*rare* passage, which might carry on the communication required, until the other was open. Now this is the thing which is actually done in the heart:—Instead of the circuitous route through the lungs, which the blood afterwards takes before it gets from one auricle of the heart to the other, a portion of the blood passes immediately from the right auricle to the left, through a hole placed in the partition which separates these cavities. This hole anatomists call the *foramen ovale*. There is likewise another cross cut answering the same purpose, by what is called the *ductus arteriosus*, lying between the pulmonary artery and the aorta. But both expedients are so strictly temporary, that after birth the one passage is closed, and the tube which forms the other shrivelled up into a ligament. If this be not contrivance, what is?

But, forasmuch as the action of the air upon the blood in the lungs appears to be necessary to the purification of that fluid, i.e. to the life and health of the animal (otherwise the shortest route might still be the best), how comes it to pass that the *fœtus* lives, and grows, and thrives, without it? The answer is, that the blood of the *fœtus* is originally derived from the mother, and is purified in a different way. When the

animals are separated, a new necessity arises ; and to meet this necessity as soon as it occurs an organization is prepared. It is ready for its purpose ; it only waits for the atmosphere ; it begins to play the moment the air is admitted to it.

## CHAPTER XV.

## RELATIONS.

WHEN several different parts contribute to one effect, or, which is the same thing, when an effect is produced by the joint action of different instruments; the fitness of such parts or instruments to one another, for the purpose of producing by their united action the effect, is what I call *relation*; and wherever this is observed in the works of nature or of man, it appears to me to carry along with it decisive evidence of understanding, intention, art. In examining, for instance, the several parts of a *watch*, the spring, the barrel, the chain, the fusee, the balance, the wheels of various sizes, forms, and positions, what is it which would take an observer's attention, as most plainly evincing a construction, directed by thought, deliberation, and contrivance? It is the suitableness of these parts to one another; first, in the succession

and order in which they act; and, secondly, with a view to the effect finally produced. Thus, referring the spring to the wheels, our observer sees in it that which originates and upholds *their* motion; in the chain, that which transmits the motion to the fusee; in the fusee, that which communicates it to the wheels; in the conical figure of the fusee, if he refer to the spring, he sees that which corrects the inequality of its force. Referring the wheels to one another, he notices, first, their teeth, which would have been without use or meaning, if there had been only one wheel, or if the wheels had had no connexion between themselves, or common bearing upon some joint effect; secondly, the correspondence of their position, so that the teeth of one wheel catch into the teeth of another; thirdly, the proportion observed in the number of teeth of each wheel, which determines the rate of going. Referring the balance to the rest of the works, he saw, when he came to understand its action, that which rendered their motions equable. Lastly, in looking upon the index and face of the watch, he saw the use and conclusion of the mechanism, viz., marking the succession of minutes and hours; but all depending upon the motions within, all upon the system of intermediate actions between the

---

spring and the pointer. What thus struck his attention in the several parts of the watch, he might probably designate by one general name of "relation :" and observing with respect to all cases whatever, in which the origin and formation of a thing could be ascertained by evidence, that these relations were found in things produced by art and design, and in no other things, he would rightly deem of them as characteristic of such productions.—To apply the reasoning here described to the works of nature.

The animal economy is full—is made up—of these *relations*.

I. There are, first, what in one form or other belong to all animals, the parts and powers which successively act upon their *food*. Compare this action with the process of a manufactory. In men and quadrupeds, the aliment is first broken and bruised by mechanical instruments of mastication, viz., sharp spikes or hard knobs, pressing against or rubbing upon one another: thus ground and comminuted, it is carried by a pipe into the stomach, where it waits to undergo a great chemical action, which we call digestion : when digested, it is delivered through an orifice, which opens and shuts as there is occasion, into the first intestine : there, after being mixed with certain proper ingre-

dients, poured through a hole in the side of the vessel, it is further dissolved: in this state the chyle, or part which is wanted, and which is suited for animal nourishment, is strained off by the mouths of very small tubes, opening into the cavity of the intestines; thus freed from its grosser parts, the percolated fluid is carried by a long, winding, but traceable course, into the main stream of the old circulation; which conveys it, in its progress, to every part of the body. Now I say again, compare this with the process of a manufactory; with the making of cider, for example; with the bruising of the apples in the mill, the squeezing of them when so bruised in the press, the fermentation in the vat, the bestowing of the liquor thus fermented in the hogsheads, the drawing off into bottles, the pouring out for use into the glass. Let any one show me any difference between these two cases, as to the point of contrivance. That which is at present under our consideration, the “relation” of the parts successively employed, is not more clear in the last case than in the first. The aptness of the jaws and teeth to prepare the food for the stomach is, at least, as manifest, as that of the cider-mill to crush the apples for the press. The concoction of the food in the stomach is as necessary

for its future use, as the fermentation of the stum in the vat is to the perfection of the liquor. The disposal of the aliment afterwards; the action and change which it undergoes; the route which it is made to take, in order that, and until that, it arrive at its destination, is more complex indeed and intricate, but, in the midst of complication and intricacy, as evident and certain, as is the apparatus of cocks, pipes, tunnels, for transferring the cider from one vessel to another; of barrels and bottles for preserving it till fit for use, or of cups and glasses for bringing it, when wanted, to the lip of the consumer. The character of the machinery is in both cases this, that one part answers to another part, and every part to the final result.

This parallel, between the alimentary operation and some of the processes of art, might be carried further into detail. A circumstantial resemblance exists between the stomachs of gallinaceous fowls and the structure of *corn-mills*. Whilst the two sides of the gizzard perform the office of the mill-stones, and are worked by powerful muscles, the craw or crop supplies the place of the *hopper*.

When our fowls are abundantly supplied with meat they soon fill their craw, which is a

dilatation of the oesophagus: but it does not immediately pass thence into the gizzard; it always enters in very small quantities, in proportion to the progress of trituration; in like manner as, in a mill, a receiver is fixed above the two large stones which serve for grinding the corn; which receiver, although the corn be put into it by bushels, allows the grain to dribble only in small quantities into the central hole in the upper mill-stone.

But we have not done with the alimentary history. There subsists a general *relation* between the external organs of an animal by which it procures its food, and the internal powers by which it digests it. Birds of prey, by their talons and beaks, are qualified to seize and devour many species, both of other birds and of quadrupeds. The constitution of the stomach agrees exactly with the form of the members. The gastric juice of a bird of prey, of an owl, a falcon, or a kite, acts upon the animal fibre alone; it will not act upon seeds or grasses at all, and they have no gizzard. On the other hand, the conformation of the mouth of the sheep or the ox is suited for browsing upon herbage. Nothing about these animals is fitted for the pursuit of living prey. Accordingly it has been found by experiments, tried

not many years ago, with perforated balls, that the gastric juice of ruminating animals, such as the sheep and the ox, speedily dissolves vegetables, but makes no impression upon animal bodies. This accordancy is still more particular. The gastric juice even of granivorous birds will not act upon the grain whilst whole and entire. In performing the experiment of digestion with the gastric juice in vessels, the grain must be crushed and bruised before it be submitted to the menstruum; that is to say, must undergo by art without the body, the preparatory action which the gizzard exerts upon it within the body; or no digestion will take place. So strict, in this case, is the relation between the offices assigned to the digestive organ, between the mechanical operation and the chemical process.

II. The relation of the kidneys to the bladder, and of the ureters to both, i. e. of the secreting organ to the vessel receiving the secreted liquor, and the pipe laid from one to the other, for the purpose of conveying it from one to the other, is as manifest as it is amongst the different vessels employed in a distillery, or in the communications between them. The animal structure in this case being simple, and the parts easily separated, it forms an instance of corre-

lation which may be presented by dissection to every eye, or which indeed, without dissection, is capable of being apprehended by every understanding. This correlation of instruments to one another fixes intention somewhere.

Especially when every other solution is negatived by the conformation. If the bladder had been merely an expansion of the ureter, produced by retention of the fluid, there ought to have been a bladder for each ureter. One receptacle, fed by two pipes, issuing from different sides of the body, yet from both conveying the same fluid, is not to be accounted for by any such supposition as this.

III. Relation of parts to one another accompanies us throughout the whole animal economy. Can any relation be more simple, yet more convincing, than this, that the eyes are so placed as to look in the direction in which the legs move and the hands work? It might have happened very differently if it had been left to chance. There were at least three quarters of the compass out of four to have erred in. Any considerable alteration in the position of the eye, or the figure of the joints, would have disturbed the line, and destroyed the alliance between the sense and the limbs.

IV. But relation perhaps is never so striking

as when it subsists, not between different parts of the same thing but, between different things. The relation between a lock and a key is more obvious than it is between different parts of the lock. A bow was designed for an arrow, and an arrow for a bow: and the design is more evident for their being separate implements.

Nor do the works of the Deity want this clearest species of relation. The *sexes* are manifestly made for each other. They form the grand relation of animated nature; universal, organic, mechanical; subsisting like the clearest relations of art, in different individuals; unequivocal, inexplicable without design. So much so, that were every other proof of contrivance in nature dubious or obscure, this alone would be sufficient. The example is complete. Nothing is wanting to the argument. I see no way whatever of getting over it.

V. The teats of animals which give suck bear a relation to the mouth of the suckling progeny; particularly to the lips and tongue. Here also, as before, is a correspondence of parts; which parts subsist in different individuals.

THESE are *general* relations, or the relations of parts which are found, either in all animals,

or in large classes and descriptions of animals. *Particular* relations, or the relations which subsist between the particular configuration of one or more parts of certain species of animals, and the particular configuration of one or more other parts of the same animal (which is the sort of relation that is perhaps most striking), are such as the following :—

I. In the *Swan*; the web-foot, the spoon-bill, the long neck, the thick down, the gramini-vorous stomach, bear all a relation to one another, inasmuch as they all concur in one design, that of supplying the occasions of an aquatic fowl, floating upon the surface of shallow pools of water, and seeking its food at the bottom. Begin with any one of these particularities of structure, and observe how the rest follow it. The web-foot qualifies the bird for swimming; the spoon-bill enables it to graze. But how is an animal, floating upon the surface of pools of water, to graze at the bottom, except by the mediation of a long neck? A long neck accordingly is given to it. Again, a warm-blooded animal, which was to pass its life upon water, required a defence against the coldness of that element. Such a defence is furnished to the swan, in the muff in which its body is wrapped. But all this outward apparatus would have been

---

in vain, if the intestinal system had not been suited to the digestion of vegetable substances. I say suited to the digestion of vegetable substances : for it is well known, that there are two intestinal systems found in birds, one with a membranous stomach and a gastric juice, capable of dissolving animal substances alone ; the other with a crop and gizzard, calculated for the moistening, bruising, and afterwards digesting, of vegetable aliment.

Or set off with any other distinctive part in the body of the swan ; for instance, with the long neck. The long neck, without the web-foot, would have been an encumbrance to the bird ; yet there is no necessary connexion between a long neck and a web-foot. In fact they do not usually go together. How happens it, therefore, that they meet only when a particular design demands the aid of both ?

II. This mutual relation, arising from a subserviency to a common purpose, is very observable also in the parts of a *Mole*. The strong short legs of that animal, the palmated feet armed with sharp nails, the pig-like nose, the teeth, the velvet coat, the small external ear, the sagacious smell, the sunk protected eye, all conduce to the utilities or to the safety of its underground life. It is a special purpose,

specially consulted throughout. The form of the feet fixes the character of the animal. They are so many shovels; they determine its action to that of rooting in the ground; and everything about its body agrees with this destination. The cylindrical figure of the mole, as well as the compactness of its form, arising from the tereness of its limbs, proportionally lessens its labour; because, according to its bulk, it thereby requires the least possible quantity of earth to be removed for its progress. It has nearly the same structure of the face and jaws as a swine, and the same office for them. The nose is sharp, slender, strong; with a pair of nerves going down to the end of it. The plush covering, which, by the smoothness, closeness, and polish of the short piles that compose it, rejects the adhesion of almost every species of earth, defends the animal from cold and wet, and from the impediment which it would experience by the mould sticking to its body. From soils of all kinds the little pioneer comes forth bright and clean. Inhabiting dirt, it is of all animals the neatest.

But what I have always most admired in the mole is its *eyes*. This animal occasionally visiting the surface, and wanting, for its safety and direction, to be informed when it does so, or

---

when it approaches it, a perception of light was necessary. I do not know that the clearness of sight depends at all upon the size of the organ. What is gained by the largeness or prominence of the globe of the eye, is width in the field of vision. Such a capacity would be of no use to an animal which was to seek its food in the dark. The mole did not want to look about it; nor would a large advanced eye have been easily defended from the annoyance to which the life of the animal must constantly expose it. How indeed was the mole, working its way under ground, to guard its eyes at all? In order to meet this difficulty, the eyes are made scarcely larger than the head of a corking pin; and these minute globules are sunk so deeply in the skull, and lie so sheltered within the velvet of its covering, as that any contraction of what may be called the eye-brows, not only closes up the apertures which lead to the eyes, but presents a cushion, as it were, to any sharp or protruding substance which might push against them. This aperture, even in its ordinary state, is like a pin-hole in a piece of velvet, scarcely pervious to loose particles of earth.

Observe then, in this structure, that which we call relation. There is no natural connexion between a small sunk eye and a shovel palmated

foot. Palmated feet might have been joined with goggle eyes; or small eyes might have been joined with feet of any other form. What was it therefore which brought them together in the mole? That which brought together the barrel, the chain and the fusee, in a watch,—design; and design in both cases, inferred from the relation which the parts bear to one another in the prosecution of a common purpose. As hath already been observed, there are different ways of stating the relation, according as we set out from a different part. In the instance before us, we may either consider the shape of the feet, as qualifying the animal for that mode of life and habitation to which the structure of its eyes confines it; or we may consider the structure of the eye, as the only one which would have suited with the action to which the feet are adapted. The relation is manifest, whichever of the parts related we place first in the order of our consideration. In a word; the feet of the mole are made for digging; the neck, nose, eyes, ears, and skin, are peculiarly adapted to an underground life; and this is what I call relation.

## CHAPTER XVI.

COMPENSATION.

COMPENSATION is a species of relation. It is

ELEPHANT,  
Discharging water from his proboscis.

relation when the *defects* of one part, or of one

organ, are supplied by the structure of another part, or of another organ. Thus,

I. The short unbending neck of the *Elephant* is compensated by the length and flexibility of his *proboscis*. He could not have reached the ground without it; or, if it be supposed that he might have fed upon the fruit, leaves, or branches of trees, how was he to drink? Should it be asked, Why is the elephant's neck so short? it may be answered, that the weight of a head so heavy could not have been supported at the end of a longer lever. To a form, therefore, in some respects necessary, but in some respects also inadequate to the occasion of the animal, a supplement is added, which exactly makes up the deficiency under which he laboured.

If it be suggested that this *proboscis* may have been produced, in a long course of generations, by the constant endeavour of the elephant to thrust out his nose (which is an hypothesis by which it has been attempted to account for the forms of animated nature), I would ask, How was the animal to subsist in the meantime, during the process, *until* this prolongation of snout were completed? What was to become of the individual whilst the species was perfecting?

Our business at present is, simply to point out

the relation which this organ bears to the peculiar figure of the animal to which it belongs, and to its mode of obtaining food to supply its bulky frame ; which is not only by browsing on grass, but also on the foliage of trees. And herein all things correspond. The necessity of the elephant's proboscis arises from the shortness of his neck ; the shortness of the neck is rendered necessary by the weight of the head. Were we to enter into an examination of the structure and anatomy of the proboscis itself, we should see in it one of the most curious of all examples of animal mechanism. It is tubular, endowed with enormous muscular power, and with the most delicate sensitiveness at its extremity. Its possessor can, with it, gather its food, rend large branches of trees, or, with its delicate finger-like end, pick up a straw or a sixpence. It is the hand by which food and drink are conveyed to the mouth, and the pump with which it can syringe its huge body : it is also a weapon of defence, wherewith it can crush, in its powerful grasp, whatever it seizes, or hurl an enemy to the ground, to be gored with its long tusks, or trampled to death beneath its ponderous feet. These properties of the same organ, taken together, exhibit a specimen, not only of design (which is attested by the ad-

vantage), but of consummate art, and, as I may say, of elaborate preparation, in accomplishing that design.

II. The hook in the wing of a *Bat* is strictly a

THE VAMPIRE BAT OF JAVA (*Pteropus Javanicus*),  
Hanging by its hooked thumbs from a branch.

mechanical, and also a *compensating* contrivance. At the angle of its wing, attached to its short thumb, there is a bent nail or claw, exactly in the form of a hook, by which the bat attaches itself to

the sides of rocks, caves, and buildings, laying hold of crevices, joinings, chinks and roughnesses. It hooks itself by this claw; remains suspended by this hold; takes its flight from this position: which operations compensate for the inaptitude

THE CRANE.

of its legs and feet for standing or walking. These inabilities are made up to her by the contrivance in her wing; and in placing a claw on that part, the Creator has deviated from the analogy observed in winged animals; and has

thus supplied her, so to speak, with the means of roosting in safety.

III. The *Crane-kind* are to live and seek their food amongst the waters ; yet, having no web-feet, are incapable of swimming. To make up for this deficiency, they are furnished with long legs for wading, or long bills for groping ; or usually with both. This is *compensation*. But I think the true reflection upon the present instance is, how every part of nature is tenanted by appropriate inhabitants. Not only is the surface of deep waters peopled by numerous tribes of birds that swim, but marshes and shallow pools are furnished with hardly less numerous tribes of birds that wade.

IV. The *tongues* of *Birds* are not constructed as organs of taste, which sense in this class is imperfectly developed ; but they are specially employed in obtaining and preparing their food for swallowing. For this purpose the tongue is supported by two small bones extending upward from the hyoid, and possesses a thick horny covering. In the parrot it can be opposed to the hooked upper mandible, as our thumb is to the fingers : in birds which feed on honey the tip of the tongue is provided with a filamentous tuft, like a camel-hair brush, by which it gathers its food : in the woodpecker it is prolonged into a

sharp lance, wherewith to reach and pierce its prey,—an arrangement which is aided by the viscid saliva which is poured out beneath the point of the tongue. The parrot's beak is not

THE COMMON PARROT.

adapted for picking up grain, but it is strong enough to crush hard substances, and hooked to help it to climb.

V. The *Spider's web* is a compensating contrivance. The spider lives upon flies, without wings

to pursue them ; a case one would have thought of great difficulty, yet provided for, and provided for by a resource which no stratagem, no

HEAD OF A BEE,

Very greatly magnified, showing the number of lenses in each eye-ball. On one side a portion of the lenses has been removed, to show their depth and prism-like shape.

effort of the animal, could have produced, had not both its external and internal structure been specifically adapted to the operation.

VI. In many species of insects the eye is

fixed, and consequently without the power of turning the pupil to the object. This great defect is, however, perfectly *compensated*; and by a mechanism which we should not suspect. The eye is a multiplying glass, with a lens looking in every direction and catching every object. By which means, although the orb of the eye be stationary, the field of vision is as ample as that of other animals, and is com-

EYES OF A BEE.

SECTION OF AN INSECT'S EYE,  
Showing the nerve.

manded on every side. When this lattice-work was first observed, the multiplicity and minuteness of the surfaces must have added to the surprise of the discovery. In the common house-fly there are as many as 4000; and in butterflies as many as 17,000 have been counted; and each hexagonal facet is a perfect eye, with its particular cornea, lens, iris, and pupil.

VII. In the chameleon, instead of there being

two eyelids, the eye is covered by an eyelid with a hole in it. This singular structure appears to be *compensatory*, and to answer to some other singularities in the shape of the animal. The neck of the chameleon is inflexible. To make up for this, the eye is so prominent as that more than half of the ball stands out of the head; by means of which extraordinary projection, the pupil of the eye can be carried by the muscles in every direction, and each eye separately is capable of being pointed towards any object. But then, so unusual an exposure of the globe of the eye requires, for its lubricity and defence, a more than ordinary protection of eyelid, as well as a more than ordinary supply of moisture; yet the motion of an eyelid formed according to the common construction, would be impeded, as it should seem, by the convexity of the organ. The aperture in the lid meets this difficulty. It enables the animal to keep the principal part of the surface of the eye under cover, and to preserve it in a due state of humidity by the movement of the eye itself.

VIII. But the works of the Deity are known by expedients. Where we should look for absolute destitution; where we can reckon up nothing but wants; some contrivance always comes in to

---

supply the privation. A *Snail*, without wings, feet, or thread, climbs up the stalks of plants, by the sole aid of a viscid humour discharged from her skin. She adheres to the stems, leaves, and fruits of plants, by means of a sticking-plaster. A fly can walk on the ceiling in virtue of its having suckers in its feet. A *mussel*, which might seem, by its helplessness, to lie at the mercy of every wave that went over it, has the singular power of spinning strong tendinous threads, by which she moors her shell to rocks and timbers. A *cockle*, on the contrary, by means of its stiff foot, works for itself a shelter in the sand. The provisions of nature extend to cases the most desperate. A *Lobster* has in its constitution a difficulty so great, that one could hardly conjecture beforehand how nature would dispose of it. In most animals, the skin grows with their growth. If, instead of a soft skin, there be a shell, still it admits of a gradual enlargement. If the shell, as in the tortoise, consist of several pieces, the accession of substance is made at the sutures. Bivalve shells grow bigger by receiving an accretion at their edge; it is the same with spiral shells at their mouth. The simplicity of their form admits of this. But the lobster's shell being applied to the limbs of the body, as well as to the body itself, being in fact the levers on

which the muscles act, and also a protecting covering, allows not of either of the modes of growth which are observed to take place in other shells. Its hardness resists expansion; and its complexity renders it incapable of increasing its size by addition of substance to its edge. How then was the growth of the lobster to be provided for? Was room to be made for it in the old shell, or was it to be successively fitted with new ones? If a change of shell became necessary, how was the lobster to extricate himself from his present confinement? how was he to uncase his buckler, or draw his legs out of his boots? The process has been observed to take place in the following way. At certain seasons, usually the autumn, the animal retires, and its shell becomes loosened, a soft covering being developed beneath the old shell. When the shell has thus become loose upon the body, the animal makes many efforts, and by a tremulous, spasmodic motion, casts it off, and subsequently withdraws its limbs from their casing. In this state, the liberated but defenceless fish retires into holes in the rock. Then a fresh concretion upon the surface, i.e. a new shell, is formed on the soft covering, adapted in every part to the increasing dimensions of the animal. This wonderful mutation is repeated every year.

The shells of the crustacea are very brittle, and therefore liable to fracture from accidental collision with hard substances. When a limb is thus injured, the means of repair which exist in a living bone are absent. This defect is compensated for by a remarkable provision : the lobster, for example, casts off a maimed and useless member, which is replaced by the gradual production of a new limb in its place. This act of self-mutilation appears to be voluntary.

If there be imputed defects without compensation, I should suspect that they were defects only in appearance. Thus, the body of the *Sloth* has often been reproached for the slowness of its motions, which has been attributed to an imperfection in the formation of its limbs. But, as already remarked, the structure of the animal is adapted to its habits ; and the great arteries of its limbs have a remarkable arrangement, subdividing and reuniting, which is evidently associated with its long-continued efforts in clinging to the branches on which it feeds.

Or there may be cases in which a defect is artificial, and compensated by the very cause which produces it. Thus the *Sheep*, in the domesticated state in which we see it, is destitute of the ordinary means of defence or escape ; is incapable either of resistance or flight. But this

is not so with the wild animal. The natural sheep is swift and active: and if it lose these qualities when it comes under the subjection of man, the loss is compensated by his protection. Perhaps there is no species of quaduped whatever which suffers so little as this does from the depredation of animals of prey.

For the sake of making our meaning better understood, we have considered this business of compensation under certain *particularities* of constitution, in which it appears to be most conspicuous. This view of the subject necessarily limits the instances to single species of animals. But there are compensations, perhaps not less certain, which extend over large classes, and to large portions of living nature.

I. In the matter of clothing, for example, the absence of hair or fur is compensated for by the thickness of the cuticle, a scaly armour, or spines. In the warm-blooded whale a remarkable provision exists for preserving its temperature, even in arctic seas, in the enormous accumulation of fat beneath the skin.

II. In quadrupeds, the deficiency of certain teeth is usually accompanied by the faculty of rumination. The sheep, deer, and ox tribe, are without fore-teeth in the upper jaw. These ruminate. The horse and ass are furnished with

teeth in the upper jaw, and do not ruminate. In the former class, the grass and hay descend into the stomach nearly in the state in which they are cropped from the pasture, or gathered from the bundle. In the paunch, or first stomach, they are softened by maceration. Thus softened and rendered tender, they are returned a second time to the action of the mouth, where the grinding teeth complete at their leisure the trituration which is necessary, but which was before left imperfect. I say, the trituration which is necessary; for it appears that the gastric fluid has an imperfect action in digesting plants, unless they have been previously masticated and mixed with saliva; but that when once vegetables are reduced to pieces by mastication, the fluid then exerts upon them its specific and complete operation. Its first effect is to soften them, and to destroy their natural consistency; it then goes on to dissolve them; not sparing even the toughest parts, such as the fibres of the leaves.

I think it very probable, that the gratification also of the animal is renewed and prolonged by this faculty. Sheep, deer, and oxen, appear to be in a state of enjoyment whilst they are chewing the cud. It is then, perhaps, that they best relish their food.

III. In birds, the *compensation* is still more striking. They have no teeth at all. What have they then to make up for this severe want? I speak of granivorous and herbivorous birds; such as common fowls, turkeys, ducks, geese, pigeons, &c. for it is concerning these alone that the question need be asked. All these are furnished with a peculiar and most powerful muscle, called the *gizzard*; the inner coat of which is fitted up with hard, rough plaits, which, by a strong friction against one another, break and grind the hard aliment as effectually, and by the same mechanical action, as a coffee-mill would do. It has been proved by the most correct experiments, that the gastric juice of these birds will not operate upon the *entire* grain; not even when softened by water or macerated in the crop. Therefore, without a grinding machine within its body, without the trituration of the gizzard, a chicken would have starved upon a heap of corn. Yet why should a bill and a gizzard go together? Why should a gizzard never be found where there are teeth?

Nor does the gizzard belong to birds as such. A gizzard is not found in birds of prey. *Their* food requires not to be ground down in a mill. The compensatory contrivance goes no further than the necessity. In both classes of birds, how-

---

ever, the digestive organ within the body bears a strict and mechanical relation to the external instruments for procuring food. The soft membranous stomach accompanies a hooked, notched beak; short muscular legs; strong, sharp, crooked talons: the cartilaginous stomach attends that conformation of bill and toes, which restrains the bird to the picking of seeds, or the cropping of plants.

IV. But to proceed with our *compensations*.— A very numerous and comprehensive tribe of terrestrial animals are entirely without feet; yet locomotive; and in a very considerable degree swift in their motion. How is the *want of feet* compensated? It is done by the disposition of the muscles and fibres of the trunk; and this zig-zag movement is aided in *snakes* by the arrangement of their scaly covering, and the wonderful mobility of their ball-and-socket jointed vertebræ and ribs. In consequence of the just collocation, and by means of the joint action of longitudinal and annular fibres, that is to say, of strings and rings, the body and train of worms are capable of being reciprocally shortened and lengthened, drawn up and stretched out. The result of this action is a progressive, and, in some cases, a rapid movement of the whole body, in any direction.

to which the will of the animal determines it. The meanest creature is a collection of wonders. The play of the rings in an *earthworm*, as it crawls; the undulatory motion propagated along the body; the beards or prickles with which the annuli are armed, and which the animal can either shut up close to its body, or let out to lay hold of the roughness of the surface upon which it creeps; and the power arising from all these, of changing its place and position, affords, when compared with the provisions for motion in other animals, proofs of new and appropriate mechanism. Suppose that we had never seen an animal move upon the ground without feet, and that the problem was, muscular action, i. e. reciprocal contraction and relaxation being given, to describe how such an animal might be constructed, capable of voluntarily changing place. Something, perhaps, like the organization of reptiles might have been hit upon by the ingenuity of an artist; or might have been exhibited in an automaton, by the combination of springs, spiral wires, and ringlets; but to the solution of the problem would not be denied, surely, the praise of invention and of successful thought: least of all could it ever be questioned, whether intelligence had been employed about it or not.

## CHAPTER XVII.

### THE RELATION OF ANIMATED BODIES TO INANIMATE NATURE.

WE have already considered *relation*, and under different views; but it was the relation of parts to parts, of the parts of an animal to other parts of the same animal, or of another individual of the same species.

But the bodies of animals hold, in their constitution and properties, a close and important relation to natures altogether external to their own; to inanimate substances, and to the specific qualities of these, e. g. *they hold a strict relation to the medium by which they are surrounded.*

I. Can it be doubted, whether the *wings of birds* bear a relation to air, and the *fins of fish* to water? They are instruments of motion, severally suited to the properties of the medium in which the motion is to be performed: which properties are different. Was not this difference contemplated, when the instruments were differently constituted?

II. The structure of the animal *ear* depends for its use not simply upon being surrounded by a fluid, but upon the specific nature of that fluid. Every fluid would not serve; its particles must repel one another; it must form an elastic medium: for it is by the successive pulses of *such* a medium, that the undulations excited by the sounding body are carried to the organ; that a communication is formed between the object and the sense; which must be done before the internal machinery of the ear, subtile as it is, can act at all.

III. The *organs* of voice and respiration are, no less than the ear, indebted for the success of their operation to the peculiar qualities of the fluid in which the animal is immersed. They therefore are constituted upon the supposition of such a fluid, i. e. of a fluid with particular properties, being always present. Change the properties of the fluid, and the organ cannot act; change the organ, and the properties of the fluid would be lost. The structure therefore of our organs, and the properties of our atmosphere, are made for one another. Nor does it alter the relation, whether you allege the organ to be made for the element (which seems the most natural way of considering it), or the element as prepared for the organ.

IV. But there is another medium with which we have to do ; with properties of its own ; with laws of acting, and of being acted upon, totally different from those of air and water ; and that is the medium through which *light* is propagated. To this new, this singular element ; to qualities perfectly peculiar, perfectly distinct and remote from the qualities of any other substance with which we are acquainted ; an organ is adapted, an instrument is correctly adjusted, not less peculiar amongst the parts of the body, not less singular in its form and in the substance of which it is composed, not less remote from the materials, the model, and the analogy of any other part of the animal frame, than the element to which it relates is specific amidst the substances with which we converse. If this does not prove appropriation, I desire to know what would prove it.

Yet the motion of this element which we call light, and the organ of vision, however related in their office and use, have no connexion whatever in their original. The action of ray of light upon the surfaces of animals has no tendency to breed eyes in their heads. The sun might shine for ever upon living bodies without the smallest approach towards producing the sense of sight. On the other

hand also, the animal eye does *not* generate or emit light.

V. Throughout the universe there is a wonderful *proportioning* of one thing to another. The size of animals, of the human animal especially, when considered with respect to other animals, or to the plants which grow around him, is such, as a regard to his conveniency would have pointed out. A giant or a pigmy could not have milked goats, reaped corn, or mowed grass ; we may add, could not have rode a horse, trained a vine, shorn a sheep ; with the same bodily ease as we do, if at all. A pigmy would have been lost amongst rushes, or carried off by birds of prey.

VI. Again (and which includes a vast variety of particulars, and those of the greatest importance) ; how close is the *suitableness* of the earth and sea to their several inhabitants ; and of these inhabitants, to the places of their appointed residence !

Take the *earth* as it is ; and consider the correspondence of the powers of its inhabitants with the properties and condition of the soil which they tread. Take the inhabitants as they are ; and consider the substances which the earth yields for their use. They can scratch its surface, and its surface supplies all which they want. This is the length of their faculties ;

and such is the constitution of the globe, and their own, that this is sufficient for all their occasions.

When we pass from the earth to the *sea*, from land to water, we pass through a great change; but an adequate change accompanies us, of animal forms and functions, of animal capacities and wants; so that *correspondency* remains. The earth in its nature is very different from the sea, and the sea from the earth; but one accords with its inhabitants as exactly as the other.

VII. The last relation of this kind which I shall mention, is that over the greater part of the earth of *sleep* to *night*; and it appears to me to be a relation which was expressly intended. Two points are manifest; first, that the animal frame requires sleep; secondly, that night brings with it a silence and a cessation of activity, which allows of sleep being taken without interruption, and without loss. Animal existence is made up of action and slumber; nature has provided a season for each. An animal which stood not in need of rest would always live in day-light. An animal which, though made for action, and delighting in action, must have its strength repaired by sleep, meets by its constitution the

returns of day and night. In the human species, for instance, were the bustle, the labour, the motion of life upheld by the constant presence of light, sleep could not be enjoyed without being disturbed by noise, and without expense of that time which the eagerness of private interest would not contentedly resign. It is happy therefore for this part of the creation, I mean that it is conformable to the frame and wants of their constitution, that nature, by the very disposition of her elements, has commanded, as it were, and imposed upon them over the largest portion of the globe at moderate intervals, a general intermission of their toils, their occupations, and pursuits.

But it is not for man, either solely or principally, that night is made. Inferior, but less perverted natures taste its solace, and expect its return with greater exactness and advantage than he does. I have often observed, and never observed but to admire, the satisfaction no less than the regularity, with which the greatest part of the irrational world yield to this soft necessity, this grateful vicissitude; how comfortably the birds of the air, for example, address themselves to the repose of the evening; with what alertness they resume the activity of the day!

Nor does it disturb our argument to confess, that certain species of animals are in motion during the night, and at rest in the day. With respect even to them, it is still true, that there is a change of condition in the animal, and an external change corresponding with it. There is still the relation, though inverted. The fact is, that the repose of other animals sets these at liberty, and invites them to their food or their sport.

If the relation of *sleep* to *night*, and in some instances its converse, be real, we cannot reflect without amazement upon the extent to which it carries us. Day and night are things close to us; the change applies immediately to our sensations; of all the phenomena of nature, it is the most obvious and the most familiar to our experience; but in its cause, it belongs to the great motions which are passing in the heavens. Whilst the earth glides round her axis, she ministers to the alternate necessities of the animals dwelling upon her surface, at the same time that she obeys the influence of those attractions which regulate the order of many thousand worlds. The relation, therefore, of sleep to night, is the relation of the inhabitants of the earth to the rotation of their globe; probably it is more; it is a relation to the system, of which that globe

is a part ; and still further, to the congregation of systems, of which theirs is only one. If this account be true, it connects the meanest individual with the universe itself ; a chicken roosting upon its perch, with the spheres revolving in the firmament.

VIII. But if any one object to our representation, that the succession of day and night, or the rotation of the earth upon which it depends, is not resolvable into central attraction, we will refer him to that which certainly is,—to the change of the seasons. Now the constitution of animals, susceptible of torpor, bears a relation to winter, similar to that which sleep bears to night. Against not only the cold, but the want of food which the approach of winter induces, the Preserver of the world has provided in many animals by migration, in many others by torpor. As one example out of a thousand ; the bat, if it did not sleep through the winter, must have starved, as the moths and flying insects upon which it feeds disappear. But the transition from summer to winter carries us into the very midst of physical astronomy, that is to say, into the midst of those laws which govern the solar system at least, and probably all the heavenly bodies.

## CHAPTER XVIII.

## INSTINCTS.

THE order may not be very obvious, by which I place *instincts* next to relations. But I consider them as a species of relation. They contribute, along with the animal organization, to a joint effect, in which view they are related to that organization. In many cases they refer from one animal to another animal ; and, when this is the case, become strictly relations in a second point of view.

An INSTINCT is a propensity prior to experience, and independent of instruction. We contend that it is by *instinct* that the sexes of animals seek each other ; that animals cherish their offspring ; that the young quadruped is directed to the teat of its dam ; that birds build their nests, and brood with so much patience upon their eggs ; that insects which do not sit upon their eggs, deposit them in those particular situations in which the young, when hatched, find their appropriate food ; that it is instinct

which carries the salmon, and some other fish, out of the sea into rivers, for the purpose of shedding their spawn in fresh water.

We may select out of this catalogue the incubation of eggs. I entertain no doubt, but that a couple of sparrows, hatched in an oven, and kept separate from the rest of their species, would proceed as other sparrows do, in every office which related to the production and preservation of their brood. Assuming this fact, the thing is inexplicable upon any other hypothesis than that of an instinct impressed upon the constitution of the animal. For, first, what should induce the female bird to prepare a nest before she lays her eggs? It is in vain to suppose her to be possessed of the faculty of reasoning; for no reasoning will reach the case. The fulness or distension which she might feel in a particular part of her body, from the growth and solidity of the egg within her, could not possibly inform her that she was about to produce something, which, when produced, was to be preserved and taken care of. Prior to experience there was nothing to lead to this inference, or to this suspicion. The analogy was *all* against it; for, in every other instance, what issued from the body was cast out and rejected.

But, secondly, let us suppose the egg to be produced into day; how should birds know that their eggs contain their young? There is nothing, either in the aspect or in the internal composition of an egg, which could lead even the most daring imagination to conjecture, that it was hereafter to turn out from under its shell a living perfect bird. The form of the egg bears not the rudiments of a resemblance to that of the bird. Inspecting its contents, we find still less reason, if possible, to look for the result which actually takes place. If we should go so far, as, from the appearance of order and distinction in the disposition of the liquid substances which we noticed in the egg, to guess that it might be designed for the abode and nutriment of an animal (which would be a very bold hypothesis), we should expect a tadpole dabbling in the slime, much rather than a dry winged, feathered creature; a compound of parts and properties impossible to be used in a state of confinement in the egg, and bearing no conceivable relation, either in quality or material, to anything observed in it. From the white of an egg, would any one look for the feathers of a goldfinch? or expect, from a simple uniform mucilage, the most complicated of all machines, the most diversified of all collections of sub-

stances? Nor would the process of incubation, for some time at least, lead us to suspect the event. Who that saw red streaks shooting in the fine membrane which divides the white from the yolk, would suppose that these were about to become bones and limbs? Who, that espied the minute pulsating point which appears after two days of incubation, could anticipate that it was so soon to become a heart, the centre of a complete circulation? It is difficult to strip the mind of its experience. It is difficult to resuscitate surprise, when familiarity has once laid the sentiment asleep. But could we forget all that we know, and which our sparrows never knew, about oviparous generation; could we divest ourselves of every information, but what we derived from reasoning upon the appearances or quality discovered in the objects presented to us, I am convinced that Harlequin, coming out of an egg upon the stage, is not more astonishing to a child, than the hatching of a chicken both would be, and ought to be, to a philosopher.

But admit the sparrow by some means to know, that within that egg was concealed the principle of a future bird; from what chemist was she to learn, that *warmth* was necessary to bring it to maturity, or that the degree of

---

warmth, imparted by the temperature of her own body, was the degree required ?

To suppose, therefore, that the female bird acts in this process from a sagacity and reason of her own, is to suppose her to arrive at conclusions which there are no premisses to justify. If our sparrow, sitting upon her eggs, expects young sparrows to come out of them, she forms, I will venture to say, a wild and extravagant expectation, in opposition to present appearances and to probability. She must have penetrated into the order of nature, further than any faculties of ours will carry us ; and it hath been well observed that this deep sagacity, if it be sagacity, subsists in conjunction with great stupidity, even in relation to the same subject. “A chemical operation,” says Addison, “could not be followed with greater art or diligence, than is seen in hatching a chicken ; yet is the process carried on without the least glimmering of thought or common sense. The hen will mistake a piece of chalk for an egg ; is insensible of the increase or diminution of their number ; does not distinguish between her own and those of another species ; is frightened when her supposititious breed of ducklings take the water.”

But it will be said, that what reason could not

do for the bird, observation, or instruction, or tradition, might. Now, if it be true that a couple of sparrows, brought up from the first in a state of separation from all other birds, would build their nest and brood upon their eggs, then there is an end of this solution. What can be the traditional knowledge of a chicken hatched in an oven ?

Of young birds, taken in their nests, a few species breed when kept in cages ; and they which do so build their nests nearly in the same manner as in the wild state, and sit upon their eggs. This is sufficient to prove an instinct, without having recourse to experiments upon birds hatched by artificial heat, and deprived from their birth of all communication with their species ; for we can hardly bring ourselves to believe, that the parent bird informed her unfeathered pupil of the history of her gestation, her timely preparation of a nest, her exclusion of the eggs, her long incubation, and of the joyful eruption at last of her expected offspring ; all which the bird in the cage must have learnt in her infancy, if we resolve her conduct into initiation and instruction.

Unless we will rather suppose that she remembers her own escape from the egg ; had attentively observed the conformation of the

---

nest in which she was nurtured ; and had treasured up her remarks for future imitation : which is not only extremely improbable, (for who, that sees a brood of callow birds in their nest, can believe that they are taking a plan of their habitation ?) but leaves, unaccounted for, one principal part of the difficulty, “ the preparation of the nest before the laying of the egg.” This she could not gain from observation in her infancy.

It is remarkable also, that the hen sits upon eggs which she has laid without any communication with the male, and which are therefore necessarily unfruitful ; that secret she is not let into. Yet, if incubation had been a subject of instruction or of tradition, it should seem that this distinction would have formed part of the lesson ; whereas the instinct of nature is calculated for a state of nature ; the exception here alluded to taking place chiefly, if not solely, amongst domesticated fowls, in which nature is forced out of her course.

There is another case of oviparous economy, which is still less likely to be the effect of education than it is even in birds, namely, that of *moths* and *butterflies*, which deposit their eggs on the precise substance, that of a cabbage for example, from which not the butterfly herself, but

the caterpillar which is to issue from her egg, draws its appropriate food. The butterfly cannot taste the cabbage. Cabbage is no food for her ; yet in the cabbage, not by chance, but studiously and electively, she lays her eggs. There are, amongst many other kinds, the willow-caterpillar and the cabbage-caterpillar ; but we do not find upon a willow the caterpillar which eats the cabbage ; nor the converse : yet, occasionally some caterpillars will change one plant for another. This choice, as appears to me, cannot in the butterfly proceed from instruction. She had no teacher in her caterpillar state. She never knew her parent. I do not see, therefore, how knowledge acquired by experience, if it ever were such, could be transmitted from one generation to another. There is no opportunity either for instruction or imitation. The parent race is gone before the new brood is hatched. And if it be original reasoning in the butterfly, it is profound reasoning indeed. She must remember her caterpillar state, its tastes and habits ; of which memory she shows no signs whatever. She must conclude from analogy (for here her recollection cannot serve her), that the little round body, which drops from her abdomen, will at a future period produce a living creature, not like herself, but like the caterpillar which she remembers

herself once to have been. Under the influence of these reflections, she goes about to make provision for an order of things, which she concludes will, some time or other, take place. And it is to be observed that not a few out of many, but that all butterflies argue thus; all draw this conclusion; all act upon it.

But suppose the address and the selection and the plan, which we perceive in the preparations which many irrational animals make for their young, to be traced to some probable origin; still there is left to be accounted for, that which is the source and foundation of these phenomena, that which sets the whole at work, the *στοργή*, the parental affection, which I contend to be inexplicable upon any other hypothesis than that of instinct.

For we shall hardly, I imagine, in brutes, refer their conduct towards their offspring to a sense of duty, or of decency, a care of reputation, a compliance with public manners, with public laws, or with rules of life built upon a long experience of their utility. And all attempts to account for the parental affection from association, I think, fail. With what is it associated? Most immediately with the throes of parturition. The more remote, but not less strong, association, that which depends upon analogy, is all against

it. Everything else, which proceeds from the body, is cast away and rejected. In birds, is it the egg which the hen loves? or is it the expectation which she cherishes of a future progeny that keeps her upon her nest? What cause has she to expect delight from her progeny? Can any rational answer be given to the question why, prior to experience, the brooding hen should look for pleasure from her chickens? It does not, I think, appear that the cuckoo ever knows her young; yet, in her way, she is as careful in making provision for them as any other bird. She does not leave her egg in every hole.

The salmon suffers no surmountable obstacle to oppose her progress up the stream of fresh rivers. And what does she do there? She sheds a spawn, which she immediately quits in order to return to the sea; and this issue of her body she never afterwards recognizes in any shape whatever. Where shall we find a motive for her efforts and her perseverance? Shall we seek it in argumentation, or in instinct? The violet crab of Jamaica performs a fatiguing march of some months' continuance, from the mountains to the sea-side. When she reaches the coast, she casts her spawn into the open sea; and sets out upon her return home: thus also exemplifying the remarkable faculty in animals generally,

---

which is denied to man, of directing themselves towards their homes.

Moths and butterflies, as hath already been observed, seek out for their eggs those precise situations and substances in which the offspring caterpillar will find its appropriate food. That dear caterpillar the parent butterfly must never see. There are no experiments to prove that she would retain any knowledge of it, if she did. How shall we account for her conduct? I do not mean for her art and judgment in selecting and securing a maintenance for her young, but for the impulse upon which she acts. What should induce her to exert any art, or judgment, or choice, about the matter? The undisclosed grub, the animal which she is destined not to know, can hardly be the object of a particular affection, if we deny the influence of instinct. There is nothing, therefore, left to her, but that of which her nature seems incapable, an abstract anxiety for the general preservation of the species; a kind of patriotism; a solicitude lest the butterfly race should cease from the creation.

More may, perhaps, be said in favour of the cultivation of instinctive tendencies, or what may be termed self-training under the guidance of necessity, as exercising an important influence

in the development of those habits which excite our wonder and admiration as matured instincts. There can be no doubt that the cultivated exercise of instinct in a given direction in the parent often has an influence on the offspring; that acquired qualities—or, more properly speaking, the attainments dependent on the training of natural instincts—may be inherited. But allowing its full force to this explanation, it can account only for the perfection of that which originally existed as an endowment or gift, apart from experience or inheritance; and if such gift imply a giver, the perfectibility of the instinctive emotions must be regarded as an endowment, evincing as much foresight in creation, as would have been manifested by their original existence in a perfect state. At best, such argument but carries us back a step in tracing the connexion between the designer and the design. Maternal instinct is as necessary for the preservation of life as the sensation of hunger; and it is equally difficult to conceive how either can be other than an original endowment for a special purpose.

Lastly; the principle of association will not explain the discontinuance of the affection when the young animal is grown up. Association, operating in its usual way, would rather produce

a contrary effect. The object would become more necessary by habits of society ; whereas birds and beasts, after a certain time, banish their offspring ; disown their acquaintance ; seem to have even no knowledge of the objects which so lately engrossed the attention of their minds, and occupied the industry and labour of their bodies. This change, in different animals, takes place at different distances of time from the birth ; but the time always corresponds with the ability of the young animal to maintain itself ; never anticipates it. In the sparrow tribe, when it is perceived that the young brood can fly and shift for themselves, then the parents forsake them for ever ; and, though they continue to live together, pay them no more attention than they do to other birds in the same flock. I believe the same thing is true generally of gregarious quadrupeds.

In this part of the case, the variety of resources, expedients, and materials, which animals of the same species are said to have recourse to, under different circumstances, and when differently supplied, makes nothing against the doctrine of instincts. The thing which we want to account for is the propensity. The propensity being there it is probable enough that it may put the animal upon different actions, according

to different exigencies. And this adaptation of resources may look like the effect of art and consideration, rather than of instinct; but still the propensity is instinctive. Each bird selects a position for its nest, adapted to the security of its eggs, and the requirements of its young when hatched.

Nor does parental affection accompany generation by any universal law of animal organization, if such a thing were intelligible. Some animals cherish their progeny with the most ardent fondness, and the most assiduous attention; others entirely neglect them; and this distinction always meets the constitution of the young animal, with respect to its wants and capacities. In many, the parental care extends to the young animal; in others, as in oviparous fish, it is usually confined to the egg, and even, as to that, to the disposal of it in its proper element. Also, as there is generation without parental affection, so is there parental instinct, or what exactly resembles it, without generation. In the bee tribe the grub is nurtured neither by the father nor the mother, but by the neutral bee. Probably the case is the same with ants.

I am not ignorant of the theory which resolves instinct into sensation; which asserts that what appears to have a view and relation to the future,

---

is the result only of the present disposition of the animal's body, and of pleasure or pain experienced *at the time*. Thus the incubation of eggs is accounted for by the pleasure which the bird is supposed to receive from the pressure of the smooth convex surface of the shells against the abdomen, or by the relief which the mild temperature of the egg may afford to the heat of the lower part of the body, which is observed at this time to be increased beyond its usual state. This present gratification is the only motive with the hen for sitting upon her nest; the hatching of the chickens is, with respect to her, an accidental consequence. The affection of viviparous animals for their young is, in like manner, solved by the relief, and perhaps the pleasure, which they receive from giving suck. The young animal's seeking, in so many instances, the teat of its dam, is explained from its sense of smell, which is attracted by the odour of milk. The salmon's urging its way up the stream of fresh-water rivers, is attributed to some gratification or refreshment which, in this particular state of the fish's body, she receives from the change of element. Now of this theory it may be said,—

First, that of the cases which require solution, there are few to which it can be applied with

tolerable probability; that there are none to which it can be applied without strong objections, furnished by the circumstances of the case. The attention of the cow to its calf, and of the ewe to its lamb, appear to be prior to their sucking. The attraction of the calf or lamb to the teat of the dam is not explained by simply referring it to the sense of smell. What made the scent of milk so agreeable to the lamb, that it should follow it up with its nose, or seek with its mouth the place from which it proceeded? No observation, no experience, no argument could teach the new-dropped animal, that the substance from which the scent issued was the material of its food. It had never tasted milk before its birth. None of the animals, which are not designed for that nourishment, ever offer to suck or to seek out any such food. What is the conclusion, but that the sugescent parts of animals are fitted for their use, and the knowledge of that use put into them?

We assert, secondly, that, even as to the cases in which the hypothesis has the fairest claim to consideration, it does not at all lessen the force of the argument for intention and design. The doctrine of instincts is that of appetencies, *super-added* to the constitution of an animal, for the effectuating of a purpose beneficial to the species.

The above-stated solution would derive these appetencies from organization; but then this organization is not less specifically, not less precisely, and, therefore, not less evidently, adapted to the same ends, than the appetencies themselves would be upon the old hypothesis. In this way of considering the subject, sensation supplies the place of foresight; but this is the effect of contrivance on the part of the Creator. Let it be allowed, for example, that the hen is induced to brood upon her eggs by the enjoyment or relief, which, in the heated state of her abdomen, she experiences from the pressure of round smooth surfaces, or from the application of a temperate warmth. How comes this extraordinary heat or itching, or call it what you will, which you suppose to be the cause of the bird's inclination, to be felt, just at the time when the inclination itself is wanted; when it tallies so exactly with the internal constitution of the egg, and with the help which that constitution requires in order to bring it to maturity? In my opinion this solution, if it be accepted as to the fact, ought to increase, rather than otherwise, our admiration of the contrivance. A gardener lighting up his stoves, just when he wants to force his fruit, and when his trees require the heat, gives not a more certain evidence of design.

So again ; when a male and female sparrow come together, they do not meet to confer upon the expediency of perpetuating their species. As an abstract proposition, they care not the value of a barley-corn whether the species be perpetuated or not : they follow their sensations ; and all those consequences ensue, which the wisest counsels could have dictated, which the most solicitous care of futurity, which the most anxious concern for the sparrow-world, could have produced. But how do these consequences ensue ? The sensations, and the constitution upon which they depend, are as manifestly directed to the purpose which we see fulfilled by them ; and the train of intermediate effects, as manifestly laid and planned with a view to that purpose ; that is to say, design is as completely evinced by the phenomena, as it would be, even if we suppose the operations to begin, or to be carried on, from what some will allow to be alone properly called instincts, that is, from desires directed to a future end, and having no accomplishment or gratification distinct from the attainment of that end.

In a word : I should say to the patrons of this opinion, Be it so : be it, that those actions of animals which we refer to instinct are not gone about with any view to their consequences, but

---

that they are attended in the animal with a present gratification, and are pursued for the sake of that gratification alone; what does all this prove, but that the *prospection*, which must be somewhere, is not in the animal, but in the Creator!

How else can we explain, in hibernating animals, the needful preparations and provisions they make, as to place and circumstances, *in anticipation* of the necessity of so doing? Does the bee know, by experience, that it cannot gather food in winter? and why are the drones slain before winter sets in, except to diminish the number in the colony to be fed?

In treating of the parental affection in brutes, our business lies rather with the origin of the principle, than with the effects and expressions of it. Writers recount these with pleasure and admiration. The conduct of many kinds of animals towards their young has escaped no observer, no historian of nature. "How will they caress them," says Derham, "with their affectionate notes; lull and quiet them with their tender parental voice; put food into their mouths; cherish and keep them warm; teach them to pick, and eat, and gather food for themselves; and, in a word, perform the part of so many nurses, deputed by the Sovereign Lord and

Preserver of the world, to help such young and shiftless creatures!" Neither ought it, under this head, to be forgotten, how much the instinct *costs* the animal which feels it; how much a bird, for example, gives up, by sitting upon her nest; how repugnant it is to her organization, her habits and her pleasures. An animal, formed for liberty, submits to confinement in the very season when everything invites her abroad: what is more; an animal delighting in motion, made for motion, all whose motions are so easy and so free, hardly a moment at other times at rest, is, for many hours of many days together, fixed to her nest, as close as if her limbs were tied down by pins and wires. For my part I never see a bird in that situation, but I recognize an invisible hand, detaining the contented prisoner from her fields and groves, for the purpose, as the event proves, the most worthy of the sacrifice, the most important, the most beneficial.

But the loss of liberty is not the whole of what the procreant bird suffers. Harvey tells us that he has often found the female wasted to skin and bone by sitting upon her eggs.

One observation more, and I will dismiss the subject. The *pairing* of birds, and the usual *non-pairing* of beasts, forms a distinction between

---

the two classes, which shows that the conjugal instinct is modified with a reference to utility founded in the condition of the offspring. In quadrupeds the young animal draws its nutriment from the body of the dam. The male parent neither does, nor can contribute any part to its early sustentation. In the winged race the young bird is supplied by an importation of food, to procure and bring home which, in a sufficient quantity for the demand of a numerous brood, requires the industry of both parents. In this difference we see a reason for the vagrant instinct of the quadruped, and for the faithful love of the feathered mate.

## CHAPTER XIX.

## OF INSECTS.

WE are not writing a system of natural history; therefore we have not attended to the classes into which the subjects of that science are distributed. What we had to observe concerning different species of animals fell easily, for the most part, within the divisions which the course of our argument led us to adopt. There remain, however, some remarks upon the *Insect* tribe, which could not properly be introduced under any of these heads; and which therefore we have collected into a chapter by themselves. And it may be here remarked that the word “insect” is employed, for this purpose, in its popular sense, rather than in the restricted sense to which it is limited in scientific classification.

The structure and uses of different parts of Insects have been carefully investigated, notwithstanding their minuteness; and they abound

with examples of every variety of adaptation, appropriate to their modes of life and their well-being.

I. The legs, which are six in number, are usually provided with a pair of sharp, strong hooklets, by which they are enabled to cling

FOOT OF HOUSE-FLY.

Foot of House-fly, showing the sucker-flaps (*s*), and hooklets (*h*).

or climb. In many, as the common house-fly, in addition to a curved hook, each foot has a pair of small suckers, by which they are enabled to adhere to the ceiling in walking thus inverted. In others these suckers are very numerous. In leaping insects, such as the cricket or flea, the hind legs are very long and powerful: by suddenly straightening these bent limbs, the flea can leap two hundred

times its own length. In the mole-cricket the fore legs are the most developed, and their extremities are broad, being adapted to work in

THE STAG BEETLE,

Showing the true wings expanded in the act of flying, and the elytra  
which cover them when folded.

an outward direction; so that this insect readily buries itself in the ground, as does the mole,

from which it derives its name. Again, in swimming insects, as the water-beetle, it is the hinder limbs that are largest; and these are expanded at their extremities and fringed with hair, thus constituting admirable paddles or oars. These instruments of propulsion in the water-boatman enable it to row itself whilst on its back, that it may more easily watch for its prey.

In the most perfect winged insects the wings are four in number, and are very firmly attached to the sides of the chest. In the carnivorous dragon-fly, for example, these are very large and of equal length, and so efficient, as organs of flight, as to enable this beautiful insect to sustain itself for hours together in the air, seeking its prey, and to elude the pursuit of even rapid birds which, in turn, prey on it. In butterflies these wings are covered with minute scales; often of brilliant and varied colours. In beetles, as the common cockchafer, the front wings are hard and horny cases.

Again, in some flying insects, as the common house-fly, the back wings are replaced by a rudimentary appendage, which seems to assist the owner in poising itself in flight. In others the front and back wings are unequal in size; but in all there is an evident design in these variations, manifested in their relations to the

mouth and legs, and to the peculiar habits of each different order.

Probably there is no more intelligible, as there certainly is no more beautifully perfect adaptation of structure to utility and the special purpose for which it is designed, than the gauze-like sails which constitute the wings of the libellula, or dragon-fly. In lightness and strength, and in consequent fitness for flight, they excel the wings of birds. The numerous filaments, or ribs, which traverse the delicate membranous expansion in every direction to afford support and to give it form, are really delicate tubes; and the sail itself originally consists of two layers, between which this tubular network is spread out. The rapidity of movement of this beautiful mechanism surpasses calculation: yet it is equalled by the marvellous control exercised in flight, and evinced by the facility with which the insect turns in every direction, even in its most rapid movements.

We may here mention, incidentally, a singular and beautiful provision, which attends the birth of the gnat from its pupa stage of existence. The eggs of this insect are deposited on the surface of water; and here the larva becomes converted into the pupa, which is enclosed in a hard covering, and still floats on the water.

---

But how is the winged gnat to escape from this coffin, with outstretched wings fit for flight? For this purpose the pupa-case is raised above the surface of the water, and then dries and is split open lengthwise, so as to form a perfect little boat, in which the future denizen of the air floats securely, till it has stretched its untried legs and dried its limp sails in security; and then it takes leave of its frail bark for ever. These forsaken cases may be often seen on the surface of ponds or water-tubs.

II. But the different habits of insects, especially in respect of their food, demand a corresponding variation in the mouth, the construction of which is adapted accordingly; in some presenting formidable weapons of destruction, in others a delicate but no less mechanical arrangement for sucking the blood of their victims, or for imbibing the nectar with which the flowers supply them. The double jaws or *mandibles* of the former move horizontally, and are armed in some with strong tooth-like prominences, or with pointed fangs, and are sharpened in others: and with these instruments some cut or grind their food, and others remorselessly destroy their prey: they are used also, as by the bee and wasp, for constructing their homes. In

fact, there is no use, associated with their habits, to which these jaws cannot be applied; and in their employment the insect is aided by

## HEAD OF FLEA.

Head of a Flea, showing its razor-like lances (*r r*) and sheaths (*s s*), on each side of the elongated tongue.

its delicate *palpi*, or feelers, which are attached to the jaws.

The sucking mouth, in many insects, is supplied with perforating instruments, like needles or fine lancets, such as the vegetable-feeding aphis, and gnat or flea. Yet these curious weapons are but variations, in construction,

of the same type of mouth as the cutting and grinding apparatus of the beetle or dragon-fly. Indeed, the same may be said of the still more remarkable representative of the jaws, which is found in the butterfly. The proboscis, as it is often termed, of this insect is a long sucking-pump, by which it is enabled to reach and draw up its fluid food from the cups of flowers. The

PROBOSCIS OF BUTTERFLY.

structure of this pump is most intricate and beautiful, consisting of two delicate filaments, like the double lash of a whip, locked together by minute teeth, and moved by spirally arranged muscles; the whole forming a tube, through which the food is imbibed. Yet mark the economy of nature: these wanderers from flower to flower, whilst pursuing their instinctive impulse to gather food, perform the important

office of scattering the pollen whereby the plants are fertilized.

III. The *stings* of insects, though for a different purpose, are, in their structure, not unlike the piercer. The sharpness to which the point in all of them is wrought ; the temper and firmness of the substance of which it is composed ; the strength of the muscles by which it

STING OF THE BEE.  
a represents the darts ; b, the poison-bag, c, the sheath ; d, a single dart.

is darted out, compared with the smallness and weakness of the insect, and with the soft and friable texture of the rest of the body, are properties of the sting to be noticed, and not a little to be admired. The sting of a *bee* will pierce through a goat-skin glove. It penetrates the human flesh more readily than the finest point of a needle. The *action* of the sting affords an example of the union of chemistry

---

and mechanism, such as, if it be not a proof of contrivance, nothing is. First, as to the chemistry ; how highly concentrated must be the *venom*, which, in so small a quantity, can produce such powerful effects ! And in the bee we may observe that this venom is made from *honey*, the only food of the insect, but the last material from which I should have expected that an exalted poison could, by any process or digestion whatsoever, have been prepared. In the next place, with respect to the mechanism, the sting is not a simple but a compound instrument. The visible sting is in strictness only a horny sheath ; for, near to the extremity may be perceived by the microscope two minute orifices, from which orifices, in the act of stinging, and as it should seem after the point of the main sting has buried itself in the flesh, are launched out two sharp stylets, which may be called the true or proper stings, as being those along a groove in which the poison is infused into the puncture already made by the exterior sting. I have said, that chemistry and mechanism are here *united* : by which observation I meant, that all this machinery would have been useless, *telum imbelle*, if a supply of poison, intense in quality, in proportion to the smallness of the drop, had not been furnished to it by the chemi-

cal elaboration which was carried on in the insect's body; and that on the other hand, the poison, the result of this process, could not have attained its effect, or reached its enemy, if, when it was collected at the extremity of the abdomen, it had not found there a machinery fitted to conduct it to the external situations in which it was to operate, viz. an awl to bore a hole, and a syringe to inject the fluid. Yet these attributes, though combined in their action, are independent in their origin. The venom does not breed the sting; nor does the sting concoct the venom.

IV. In many species of the butterfly, the proboscis, when not in use, is coiled up like a watch-spring. In the bee, the proboscis serves the office of the mouth, the insect having no other: and how much better adapted it is, than any other form of mouth would be, for the collecting of the proper nourishment of the animal, is sufficiently evident. The food of the bee is the nectar of flowers; a drop of syrup, lodged **deep** in the bottom of the corolla, in the recesses of the petals, or down the neck of a monopetalous glove. Into these cells the bee thrusts its long narrow pump, through the cavity of which it laps and sucks up this precious fluid, inaccessible to every other approach.

---

It is observable also, that the plant is not the worse for what the bee does to it; indeed it provides for its fructification by the scattering of its pollen. The harmless plunderer rifles the sweets, but leaves the flower uninjured. The ringlets of which the proboscis of the bee is composed, the muscles by which it is extended and contracted, form so many microscopical wonders. The agility also with which it is moved can hardly fail to excite admiration. But it is enough for our purpose to observe, in general, the suitableness of the structure to the use, of the means to the end, and especially the wisdom by which nature has departed from its most general analogy (for animals being furnished with mouths are such), when the purpose could be better answered by the deviation.

We have seen the analogy that exists between the strong-jawed insects and the graminivorous and carnivorous mammalia, in the form and strength of the weapons with which they grind their food or destroy their prey: we may also notice another resemblance, and for the same purpose in each, between these insects and birds which feed on grain: the former possess a gizzard, of similar construction to the latter, and placed in close connexion with the stomach.

The sense of Touch must be, and no doubt is,

peculiarly delicate in insects. We have already noticed the *palpi*, attached to the jaws; but the *antennæ* seem to be the most sensitive feelers possessed by them; and it seems probable also that the vibratory sensations conveyed by them are appreciated as sound is by the special organ of hearing. Insects obviously smell, for they are guided to their food by this sense; but the possession of the organ cannot be satisfactorily determined. Every one must have noticed how rapidly carrion flies accumulate upon their scented meal.

The circulation and purification of the blood in insects is not of that complex character that distinguishes the higher classes of animals: the movement of the blood is undulatory; and air to purify it is admitted by numerous tubes or channels to every part of the body: and the apertures or spiracles of these tracheæ are carefully protected from the intrusion of extraneous bodies by minute hairs. By this arrangement the body of the insect is materially lightened, and the blood is freely oxygenated.

V. The *metamorphoses* of insects from grubs into moths and flies is an astonishing process. A hairy caterpillar is transformed into a butterfly. Observe the change. We have four beautiful wings, where there were none before;

---

a tubular proboscis, in the place of a mouth with jaws and substitutes for teeth; six long legs, instead of fourteen feet. In another case we see a white, smooth, soft worm turned into a black, hard, crustaceous beetle, with gauze wings. These, as I said, are astonishing processes, and must require, as it should seem, a proportionably artificial apparatus.

The process by which this change takes place varies in different insects; but usually is the following. When the egg of the butterfly or moth, for instance, is hatched, a larva or caterpillar comes forth, which grows and frequently changes its covering until it has attained its full size, when it appears under a hard covering and without limbs: this is the *pupa*. When this covering is burst the winged insect comes forth, and soon enters on its new and active existence. But during the pupa stage, the confined insect has no means of existence or growth from without; yet this difficulty is provided for, as in hibernating mammals, by an accumulation of a kind of fatty matter within the larva, which is thus stored, in anticipation of future need for the growth of the pupa.

VI. Almost all insects are oviparous. Nature usually keeps her butterflies, moths, and caterpillars locked up during the winter in their egg-

state; and we have to admire the various devices to which, if we may so speak, the same nature hath resorted, for the *security* of the egg. Many insects enclose their eggs in a silken web; others cover them with a coat of hair torn from their own bodies; some glue them together; and others, like the moth of the silk-worm, glue them to the leaves upon which they are deposited, that they may not be shaken off by the wind, or washed away by rain; some again make incisions into leaves, and hide an egg in each incision; whilst some envelope their eggs with a soft substance, which forms the first aliment of the young animal: and some again make a hole in the earth, and, having stored it with a quantity of proper food, deposit their eggs in it, or even float them on the water, firmly glued together into a little raft, as does the gnat. In all which we are to observe, that the expedient depends, not so much upon the address of the animal, as upon the physical resources of his constitution.

The art also with which the young insect is *coiled up* in the egg presents, where it can be examined, a subject of great curiosity. The insect, furnished with all the rudiments of its future members, is rolled up into a form which seems to contract it into the least possible

---

space; by which contraction, notwithstanding the smallness of the egg, it has room enough in its apartment, and to spare. This folding of the limbs appears to me to indicate a special direction; for if it were merely the effect of compression, the collocation of the parts would be more various than it is. In the same species I believe it is always the same.

These observations belong to the whole insect tribe, or to a great part of them. Other observations are limited to fewer species; but not, perhaps, less important or satisfactory.

In spiders, which are still popularly regarded as insects, each jaw is provided with a moveable poison-fang, resembling, in its arrangement and use, the poison-teeth of venomous snakes: for, when these voracious creatures seize their prey, the venom is expressed through a minute aperture at the extremity of the fang into the inflicted wound, producing almost instant death of the victim. They are aided also in entrapping their prey by the web they spin and the net they spread; but this is only one of the very many uses to which this beautiful texture is applied: and the diversified ingenuity which this application manifests is truly wonderful; and not less so is the exquisite mechanism by

which, so to speak, the yarn is spun and the ropes are made.

The spinning apparatus of the caterpillar, the silk-worm for example, is simple, consisting of a long tubular sac placed on each side of the intestine, terminating in a single orifice through which the silky thread is drawn.

I. In the spider the arrangement is more complicated. It has four *spinnerets*, each of which is pierced by innumerable orifices, so that each small cord is formed of, probably, hundreds of finer threads woven together in a most intricate way, by which the strength of the delicate web is greatly in-

SILK BAGS OF  
COSSUS CATERPILLAR.

creased. The secreting apparatus of this glue is similar to, but more complicated than, that of the caterpillar. In both cases, the extremity of the thread, by means of its adhesive quality, is first attached by the animal to some external hold ; and the end being now fastened to a point, the insect, by turning round its body, or by receding from that point, draws out the thread through the holes above described, by an operation, as hath been observed, exactly similar to the drawing of wire. The thread, like the wire, is formed by the hole through which it passes. In one respect there is a difference. The wire is the metal unaltered, except in figure. In the animal process, the nature of the substance is somewhat changed, as well as the form ; for, as it exists within the insect, it is a soft clammy gum or glue. The thread acquires its firmness and tenacity from the action of the air upon its surface, in the moment of exposure ; and a thread so fine is almost all surface. This property, however, of the paste is part of the contrivance.

The mechanism itself consists of the bags or reservoirs into which the glue is collected, and of the external holes communicating with these bags : and the action of the machine is seen in the forming of a thread, as wire is formed, by

drawing the material already prepared through holes of proper dimensions. The secretion is an act too subtle for our discernment, except as we perceive it by the produce, but one thing answers to another ; the secretory glands to the quality and consistence required in the secreted substance ; the bag to its reception : the outlets and orifices are constructed, not merely for relieving the reservoirs of their burden, but for manufacturing the contents into a form and texture, of great external use, or rather indeed of future necessity, to the life and functions of the insect.

II. BEES, under one character or other, have furnished every naturalist with a set of observations. I shall in this place confine myself to one ; and that is, the *relation* which obtains between the wax and the honey. No person, who has inspected a bee-hive, can forbear remarking how commodiously the honey is bestowed in the comb ; for the hexagonal form of each cell is that which admits of closest packing without loss of space : and, amongst other advantages, how effectually the fermentation of the honey is prevented by distributing it into small cells. The fact is, that when the honey is separated from the comb, and put into jars, it runs into fermentation with a much less

degree of heat than what takes place in a hive. This may be reckoned a nicety: but, independently of any nicety in the matter, I would ask, what could the bee do with the honey if it had not the wax? how, at least could it store it up for winter? The wax, therefore, answers a purpose with respect to the honey; and the honey constitutes that purpose with respect to the wax. This is the relation between them. But the two substances, though together of the greatest use, and without each other of little, come from a different origin. The bee finds the honey, but makes the wax. The honey is lodged in the nectaria of flowers, and probably undergoes little alteration; is merely collected: whereas the wax is a ductile, tenacious paste, which is produced by a digestive process in the body of the bee, and exudes between the joints of the abdomen. What account can be rendered of facts so circumstanced, but that the animal, being intended to feed upon honey, was, by a peculiar external configuration, enabled to procure it? That, moreover, wanting the honey when it could not be procured at all, it was further endued with the no less necessary faculty of constructing repositories for its preservation? Further, it is requisite that the larvæ or young should be fed; and their

food is not the same as that by which the winged insect is nourished, but is the pollen of flowers. A special arrangement exists for the collection of this pollen, which adheres to the thighs of the bee as it is busy among the flowers, and is carried home in the spoon-shaped appendages on its thighs, which are employed for this purpose. Thus the food of the larvæ (bee-bread) and the honey are collected, but the wax is produced by a digestive process from the honey. This is a just account of the honey, and the honey-comb: and this account, through every part, carries a creative intelligence along with it.

The *sting* also of the bee has this relation to the honey, that it is necessary for the protection of a treasure which invites so many robbers.

Our business is with mechanism. The Stag-beetle cleans its antennæ on a soft patch of hair between his foreleg and chest. Any one may watch how cleverly a common house-fly dresses his body, wings, and limbs.

III. If the reader, looking to our distributions of science, wish to contemplate the chemistry, as well as the mechanism of nature, the insect creation will afford him an example. I refer to the phosphorescent light in the tail of a *glow-worm*. The only thing to be inquired after is

the singularity, if any such there be, in the natural history of this animal, which should render a provision of this kind more necessary for it than for other insects. That singularity seems to be the difference which subsists between the male and the female. The glow-worm is a female confined to the ground, the male of which is a *fly*; lively, comparatively small, dissimilar to the female in appearance, probably also as distinguished from her in habits, pursuits, and manners, as he is unlike in form and external constitution. Here, then, is the adversity of the case. The female cannot meet her companion in the air. The winged rover despairs the ground. They might never therefore be brought together, did not this radiant torch direct the volatile mate to his sedentary female.

The light emitted by the male insect is comparatively feeble. The female has the power of varying the intensity of her light, which is most vivid at the pairing season: but as it exists at other times, it may fulfil other purposes besides that mentioned. Many insects, besides the glow-worm, especially in more southern regions than our own, possess the same remarkable property of emitting phosphorescent light at will.

In the depths of the ocean the phosphorescence of living organisms may be made available to give light. Whether it result from the combination of some combustible matter, like phosphorus, with the oxygen of the air or water ; or whether it be allied in its source with the evolution of some such agent as the electric organ of the torpedo, is unknown.

I MUST now crave the reader's permission to introduce into this place, for want of a better, an observation or two upon the tribe of animals, whether belonging to land or water, which are covered by shells.

I. The *shells of snails* are a wonderful, a mechanical, and, if one might so speak concerning the works of nature, an original contrivance. Other animals have their proper retreats, their hybernacula also, or winter-quarters, but the snail carries these about with him. He travels with his tent ; and this tent, though, as was necessary, both light and thin, is completely impervious either to moisture or air. The young snail comes out of its egg with the shell upon its back ; and the gradual enlargement which the shell receives is derived from the slime excreted by the animal's skin, or, more properly speaking, its mantle. Now the aptness

of this excretion to the purpose, its property of hardening into a shell, and the apparatus by which it is produced, are things which can, with no probability, be referred to any other cause than to express design ; and that not on the part of the animal alone, in which design, though it might build the house, could not have supplied the material. The will of the animal could not determine the quality of the excretion. Add to which, that the shell of a snail, with its pillar and convolution, is a very artificial fabric ; whilst a snail, as it should seem, is the most numb and unprovided of all artificers. In the midst of variety, there is likewise a regularity which would hardly be expected. In the same species of snail the number of turns is usually, if not always, the same. The sealing up of the mouth of the shell by the snail is also well calculated for its warmth and security ; but the cerate is not of the same substance with the shell.

II. Much of what has been observed of snails belongs to *shell-fish* and their *shells*, particularly to those of the univalve kind ; with the addition of two remarks : one of which is upon the great strength and hardness of most of these shells. I do not know whether, the weight being given, art can produce so strong a case as we find in some of these shells. Which defensive strength

suits well with the life of an animal, that has often to sustain the dangers of a stormy element, and a rocky bottom, as well as the attacks of voracious fish. The other remark is upon the property, in the animal excretion, not only of congealing, but of congealing, or, as the builder would call it, *setting*, in water, and into a cretaceous substance, firm and hard. This property is much more extraordinary, and, chemically speaking, more specific than that of hardening in the air ; which may be reckoned a kind of exsiccation, like the drying of clay into bricks.

III. In the *bivalve* order of shell-fish, cockles, muscles, oysters, &c., what contrivance can be so simple or so clear, as the insertion, at the back, of a tough elastic substance, that becomes at once the ligament which binds the two shells together, and the spring *hinge* upon which they open and shut ? The strong muscle, by which the two shells are drawn together, lies between them : when this is relaxed, the elastic spring-hinge opens the shells.

IV. The shell of a lobster's tail, in its articulations and overlappings, represents the jointed part of a coat of mail ; or, rather, which I believe to be the truth, a coat of mail is an imitation of a lobster's shell. The same end is to be answered by both ; the same properties,

therefore, are required in both ; namely, hardness and flexibility, a covering which may guard the part without obstructing its motion. For this double purpose, the art of man, expressly exercised upon the subject, has not been able to devise anything better than what nature presents to his observation. The same remark may be applied to the terrible weapons of destruction this predacious animal is provided with, for seizing and destroying its prey. Indeed, the serrated and spine-like tail of the king-crab is used by savages to point their spears. Is not this therefore mechanism, which the mechanic, having a similar purpose in view, adopts ? Is the structure of a coat of mail to be referred to art ? Is the same structure of the lobster, conduced to the same use, to be referred to anything less than art ?

Some, who may acknowledge the imitation, and assent to the inference which we draw from it in the instance before us, may be disposed, possibly, to ask why such imitations are not more frequent than they are, if it be true, as we allege, that the same principle of intelligence, design, and mechanical contrivance, was exerted in the formation of natural bodies, as we employ in the making of the various instruments by which our purposes are served ? The answers

to this question are, first, that it seldom happens that precisely the same purpose, and no other, is pursued in any works which we compare of nature and of art; secondly, that it still more seldom happens that we *can* imitate nature if we would. Our materials and our workmanship are equally deficient. Springs and wires, and cork and leather, produce a poor substitute for an arm or a hand. In the example which we have selected, I mean a lobster's shell compared with a coat of mail, these difficulties stand less in the way, than in almost any other that can be assigned: and the consequence is, as we have seen, that art gladly borrows from nature her contrivance, and imitates it closely.

BUT to return to insects. I think it is in this class of animals above all others, especially when we take in the multitude of species which the microscope discovers, that we are struck with what Cicero has called “*the insatiable variety of nature.*” There are said to be thousands of species of flies, and hundreds of butterflies and moths; each different from all the rest. Ray observed, within the compass of a mile or two of his own house, two hundred kinds of moths and butterflies, nocturnal and diurnal. He likewise asserts, but I think with-

out any grounds of exact computation, that the number of species of insects, reckoning all sorts of them, may not be short of ten thousand.<sup>1</sup> They are now ascertained to be much more numerous. And in this vast variety of animal forms (for the observation is not confined to insects, though more applicable perhaps to them than to any other class), we are sometimes led to take notice of the different methods, or rather of the studiously diversified methods, by which one and the same purpose is attained. In the article of breathing, for example, which was to be provided for in some way or other, besides the ordinary varieties of lungs, gills, and breathing-holes (for insects in general respire, not by the mouth, but through holes in the sides), the larva of the gnat is provided with fin-like appendages to the tail, which, by their movements, keep this part above water; for near to it is the orifice of the trachea, by which the larva draws in the air which is necessary. In the article of natural clothing, we have the skins of animals invested with scales, hair, feathers, mucus, froth; or itself turned into a shell or crust: in the no less necessary article of offence and defence, we have teeth, talons,

<sup>1</sup> "Wisdom of God," p. 23.

beaks, horns, stings, prickles, with (the most singular expedient for the same purpose) the power of giving the electric shock, and as is credibly related of some animals, of driving away their pursuers by an intolerable foetor, or of blackening the water through which they are pursued. The consideration of these appearances might induce us to believe, that *variety* itself, distinct from every other reason, was a motive in the mind of the Creator, or with the agents of His will.

To this great variety in organized life, the Deity has given, or perhaps there arises out of it, a corresponding variety of animal *appetites*. For the final cause of this we have not far to seek. Did all animals covet the same element, retreat, or food, it is evident how much fewer could be supplied and accommodated, than what at present live conveniently together, and find a plentiful subsistence. What one nature rejects, another delights in. Food which is nauseous to one tribe of animals becomes, by that very property which makes it nauseous, an alluring dainty to another tribe. Carrion is a treat to dogs, ravens, vultures, fish. The exhalations of corrupted substances attract flies by crowds. Maggots revel in putrefaction.

## CHAPTER XX.

OF PLANTS.

I THINK a designed and studied mechanism to be, in general, more evident in animals than in *plants*, though by no means deficient in the latter; and it is unnecessary to dwell upon a less obvious argument, where a more manifest one is at hand. There are, however, a few observations upon the vegetable kingdom, which lie so directly in our way, that it would be improper to pass them by without notice.

One great intention of nature in the structure of plants, seems to be the perfecting of the *seed*; and, what is part of the same intention, the preserving of it until it be *perfected*. This intention shows itself, in the first place, by the care which appears to be taken, to protect and ripen, by every advantage which can be given to them of situation in the plant, those parts which most immediately contribute to fructification, viz. the antheræ, the stamina, and the stigmata. These parts are usually lodged in

the centre, the recesses, or the labyrinths of the flower ; during their tender and immature state they are shut up in the stalk, or sheltered in the bud ; as soon as they have acquired firmness of texture sufficient to bear exposure, and are ready to perform the important office which is assigned to them, they are disclosed to the light and air, by the bursting of the stem, or the expansion of the petals ; after which they have, in many cases, by the very form of the flower during its blow, the light and warmth reflected upon them from the concave side of the cup. What is called also the *sleep* of plants, is the leaves or petals disposing themselves in such a manner as to shelter the young stem, buds, or fruit. They turn up, or they fall down, according as this purpose renders either change of position requisite. In the growth of corn, whenever the plant begins to shoot, the two upper leaves of the stalk are joined together, embrace the ear, and protect it till the pulp has acquired a certain degree of consistency. In some water-plants, the flowering and fecundation are carried on *within* the stem, which afterwards opens above the water to let loose the impregnated seed. The *pea* or papilionaceous tribe enclose the parts of fructification within a beautiful folding of the internal blossom, sometimes

called, from its shape, the boat or keel; itself also usually protected under a penthouse formed by the external petals. This structure is very artificial, and, what adds to the value of it, though it may diminish the curiosity, very general. It has also this further advantage (and it is an advantage strictly mechanical), that all the blossoms turn their *backs* to the wind, whenever the gale blows strong enough to endanger the delicate parts upon which the seed depends. I have observed this a hundred times in a field of peas in blossom. It is an aptitude which results from the figure of the flower, and, as we have said, is strictly mechanical; as much so as the turning of a weather-board or tin cap upon the top of a chimney. Of the wild *poppy*, and of many similar species of flowers, the head, while it is growing, hangs down, a rigid curvature in the upper part of the stem giving to it that position; and in that position it is impenetrable by rain or moisture. When the head has acquired its size, and is ready to open, the stalk *erects* itself, for the purpose, as it should seem, of presenting the flower, and with the flower, the instruments of fructification, to the genial influence of the sun's rays. This always struck me as a curious property; and specifically, as well as originally, provided

for in the constitution of the plant: for, if the stem be only bent by the weight of the head, how comes it to straighten itself when the head is the heaviest? These instances show the attention of nature to this principal object, the safety and maturation of the parts upon which the seed depends.

In *trees*, especially in those which are natives of colder climates, this point is taken up earlier. Many of these trees (observe in particular the *ash* and the *horse-chestnut*) produce the embryos of the leaves and flowers in one year, and bring them to perfection the following. There is a winter therefore to be gotten over. Now what we are to remark is, how nature has prepared for the trials and severities of that season. These tender embryos are, in the first place, wrapped up with a compactness which no art can imitate: in which state they compose what we call the bud. This is not all. The bud itself is enclosed in scales; which scales are formed from rudimentary leaves, which are never developed, but are thrown off as the young leaves expand in the spring. Neither is this the whole. In the coldest climates a third preservative is added, by the bud having a *coat* of gum or rosin, which, being congealed, resists the rain and strongest frosts. On the approach

of warm weather, this gum is softened, and ceases to be a hindrance to the expansion of the leaves and flowers. All this care is part of that system of provisions, which has for its object and consummation the production and perfecting of the seeds.

The SEEDS themselves are usually packed up in a *capsule*, a vessel composed of coats, which, compared with the rest of the flower, are strong and tough. From this vessel projects a tube, through the tissue of which the farina penetrates to the embryo seeds within the pericarp. And here also occurs a mechanical variety, accommodated to the different circumstances under which the same purpose is to be accomplished. In flowers which are erect, the pistil is shorter than the stamens; and the pollen, shed from the antheræ into the cup of the flower, is caught in its descent by the head of the pistil, called the stigma. But how is this managed when the flowers hang down (as does the crown imperial for instance), and in which position the farina, in its fall, would be carried from the stigma, and not towards it? The relative length of the parts is now inverted. The pistil in these flowers is usually longer instead of shorter than the stamens, that its protruding summit may receive the pollen as it drops to the

ground. In some cases (as in the *nigella*), where the shafts of the pistils or styles are disproportionately long, they bend down their extremities upon the antheræ, that the necessary approximation may be effected : in other instances the intervention of insects is brought into requisition for conveying the pollen to the stigma.

But (to pursue this great work in its progress) the impregnation, to which all this machinery relates, being completed, the other parts of the flower fade and drop off, whilst the *gravid seed-vessel*, on the contrary, proceeds to increase its bulk, always to a great, and in some species (in the gourd, for example, and melon), to a surprising comparative size ; assuming in different plants an incalculable variety of forms, but all evidently conducing to the security of the seed. By virtue of this process, so necessary but so diversified, we have the seed at length, in stone-fruits and nuts, incased in a strong shell, the shell itself enclosed in a pulp or husk, by which the seed within is, or hath been, fed : or, more generally (as in grapes, oranges, and the numerous kinds of berries), plunged over head in a glutinous syrup, contained within a skin or bladder : at other times (as in apples and pears) embedded in the heart of a firm fleshy substance ; or (as in strawberries) pricked into the surface of a soft pulp.

. These and many more varieties exist in what we call *fruits*.<sup>1</sup> In pulse, and grain, and grasses;

<sup>1</sup> From the conformation of fruits alone, one might be led, even without experience, to suppose, that part of this provision was destined for the utilities of animals. As limited to the plant, the provision itself seems to go beyond its object. The flesh of an apple, the pulp of an orange, the meat of a plum, the fatness of the olive, appear to be *more* than sufficient for the nourishing of the seed or kernel. The event shows, that this redundancy, if it be one, ministers to the support and gratification of animal natures; and when we observe a provision to be more than sufficient for one purpose, yet wanted for another purpose, it is not unfair to conclude that both purposes were contemplated together. It favours this view of the subject to remark, that fruits are not (which they might have been) ready all together, but that they ripen in succession throughout a great part of the year; some in summer; some in autumn; that some require the slow maturation of the winter, and supply the spring; also that the coldest fruits grow in the hottest places. Cucumbers, pine-apples, melons, are the natural produce of warm climates, and contribute greatly, by their coolness, to the refreshment of the inhabitants of those countries.

I will add to this note the following observation communicated to me by Mr. Brinkley :—

“ The eatable part of the cherry or peach first serves the purposes of perfecting the seed or kernel, by means of vessels passing through the stone, and which are very visible in a peach-stone. After the kernel is perfected the stone becomes hard, and the vessels cease their functions. But the substance surrounding the stone is not then thrown away as useless. That which was before only an instrument for perfecting the kernel, now receives and retains to itself the whole of the sun’s influence, and thereby becomes a grateful food to man. Also. what an evident

in trees, and shrubs, and flowers ; the variety of the seed-vessels is incomputable. We have the seeds (as in the pea-tribe) regularly disposed in parchment pods, which, though soft and membranous, completely exclude the wet even in the heaviest rains ; the pod also, not seldom (as in the bean) lined with a fine down ; at other times (as in the senna) distended like a brown bladder ; or we have the seed enveloped in wool (as in the cotton plant), lodged (as in pines) between the hard and compact scales of a cone, or barricadoed (as in the artichoke and thistle) with spikes and prickles ; in mushrooms, placed under a penthouse ; in ferns, within slits in the back part of the leaf : or (which is the most general organization of all) we find them covered by strong, close tunics, and attached to the stem according to an order appropriated to each plant, as is seen in the several kinds of grains and of grasses.

In which enumeration, what we have first to notice is, unity of purpose under variety of expedients. Nothing can be more *single* than the design ; more *diversified* than the means. Pellicles, shells, pulps, pods, husks, skin, scales armed with thorns, are all employed in prose-

mark of design is the stone protecting the kernel ! The intervention of the stone prevents the second use from interfering with the first."

cuting the same intention. Secondly ; we may observe that, in all these cases, the purpose is fulfilled within a just and *limited* degree. We can perceive that, if the seeds of plants were more strongly guarded than they are, their greater security would interfere with other uses. Many species of animals would suffer, and many perish, if they could not obtain access to them. The plant would overrun the soil ; or the seed be wasted for want of room to sow itself. It is sometimes as necessary to destroy particular species of plants, as it is at other times to encourage their growth. Here, as in many cases, a balance is to be maintained between opposite uses. The provisions for the preservation of seeds appear to be directed chiefly against the inconstancy of the elements, or the sweeping destruction of inclement seasons. The consumption by animals, and the injuries of accidental violence, are allowed for in the abundance of the increase. The result is, that out of the many thousand different plants which cover the earth, not a single species, under ordinary circumstances, can become extinct.

When nature has perfected her seeds, her next care is to disperse them. The seed cannot answer its purpose while it remains confined in the capsule. After the seeds therefore are

ripened, the pericarpium opens to let them out; and the opening is not like an accidental bursting, but, for the most part, is according to a certain rule in each plant. What I have always thought very extraordinary,—nuts and shells, which we can hardly crack with our teeth, divide and make way for the little tender sprout which proceeds from the kernel. Handling the nut, I could hardly conceive how the plantule was ever to get out of it. There are cases, likewise, in which the seed-vessel by an elastic jerk, at the moment of its explosion, casts the seeds to a distance. We all moreover know, that many seeds (those of most composite flowers, as of the thistle, dandelion, &c.) are endowed with what are not improperly called *wings*; that is, downy appendages, by which they are enabled to float in the air, and are carried oftentimes by the wind to great distances from the plant which produces them. It is the swelling also of this downy tuft, within the seed-vessel, that seems to overcome the resistance of its coats, and to open a passage for the seed to escape. By water also seeds have been transported more than 2000 miles from their native homes.

But the *constitution* of seeds is still more admirable than either their preservation or their

dispersion. In the body of the seed of every species of plant, or nearly of every one, provision is made for two grand purposes : first, for the safety of the *germ*; secondly, for the temporary support of the future plant. The sprout, as folded up in the seed, is delicate and brittle beyond any other substance. It cannot be touched without being broken. Yet, in beans, peas, grass-seeds, grain, fruits, it is so fenced on all sides, so shut up and protected that, whilst the seed itself is rudely handled, tossed into sacks, shovelled into heaps, the sacred particle, the miniature plant, remains unhurt. It is wonderful, also, how long many kinds of seeds, by the help of their integuments, and perhaps of their oils, stand out against decay. A grain of mustard-seed has been known to lie in the earth for a hundred years; and, as soon as it had acquired a favourable situation, to shoot as vigorously as if just gathered from the plant. Then, as to the second point, the temporary support of the future plant, the matter stands thus. In grain, and pulse, and kernels, and pippins, the germ composes a very small part of the seed. The rest consists of a nutritious substance, from which, after the change produced by warmth and moisture combined, the sprout draws its aliment for some considerable time

after it is put forth ; viz. until the fibres, shot out from the other end of the seed, are able to imbibe juices from the earth, in a sufficient quantity for its demand. It is owing to this constitution that we see seeds sprout, and the sprouts make a considerable progress without any earth at all. It is an economy, also, in which we remark a close analogy between the seeds of plants and the eggs of animals. The same point is provided for, in the same manner, in both. In the plant, as well as in the animal, the structure has every character of contrivance belonging to it : in both it breaks the transition from prepared to unprepared aliment ; in both it is prospective and compensatory. In animals which suck, this intermediate nourishment is supplied from a different source.

In all subjects, the most common observations are the best, when it is their truth and strength which have made them common. There are, of this sort, *two* concerning plants, which it falls within our plan to notice. The *first* relates to what has already been touched upon, their germination. When a grain of corn is cast into the ground, this is the process which takes place. From one end of the grain issues a green sprout ; from the other, a number of white fibrous threads. How can this be explained ? Why not sprouts

---

from both ends? why not fibrous threads from both ends? To what is the difference to be referred but to design; to the different uses which the parts are thereafter to serve; uses which discover themselves in the sequel of the process? The sprout, or plumule, struggles into the air, and becomes the plant, of which, from the first, it contained the rudiments; the fibres shoot into the earth; and thereby both fix the plant to the ground, and collect nourishment from the soil for its support. Now, what is not a little remarkable, the parts issuing from the seed take their respective directions, into whatever position the seed itself happens to be cast. If the seed be thrown into the wrongest possible position, that is, if the ends point in the ground the reverse of what they ought to do, everything, nevertheless, goes on right. The sprout, after being pushed down a little way, makes a bend, and turns upwards; the fibres, on the contrary, after shooting at first upwards, turn down. Of this extraordinary vegetable fact, the following account has been given: "The plumule (it is said) is stimulated by the *air* into action, and elongates itself when it is thus most excited; the radicle is stimulated by *moisture*, and elongates itself when *it* is thus most excited. Whence one

of these grows upward in quest of its adapted object, and the other downward." Were this account better verified by experiment than it is, it only shifts the contrivance. It does not disprove the contrivance; it only removes it a little further back. Who, to use our author's own language, "*adapted* the objects"? Who gave such a quality to these connate parts, as to be susceptible of *different* "stimulation;" as to be "*excited*" each only by its own element, and precisely by that which the success of the vegetation requires? I say "*which* the success of the vegetation requires:" for the toil of the husbandman would have been in vain; his laborious and expensive preparation of the ground in vain, if the event must, after all, depend upon the position in which the scattered seed was sown. Not one seed out of a hundred would fall in a right direction.

Our *second* observation is upon a general property of many climbing plants, which is strictly mechanical. In these plants, from each knot or joint issue, close to each other, two shoots: one bearing the flower and fruit; the other, drawn out into a wire, a long, tapering, spiral tendril, that twists itself round anything which lies within its reach. Considering that in this class two purposes are to be provided for (and

---

together), fructification and support, the fruitage of the plant, and the sustentation of the stalk, what means could be used more effectual, or, as I have said, more mechanical, than what this structure presents to our eyes? Why, or how, without a view to this double purpose, do two shoots, of such different and appropriate forms, spring from the same joint, from contiguous points of the same stalk? It never happens thus in robust plants, or in trees. "We see not (says Ray) so much as one tree, or shrub, or herb, that hath a firm and strong stem, and that is able to mount up and stand alone without assistance, *furnished with these tendrils.*" Make only so simple a comparison as that between a pea and a bean. Why does the pea put forth tendrils, the bean not; but because the stalk of the pea cannot support itself, the stalk of the bean can? We may add also, as a circumstance not to be overlooked, that in the pea-tribe these clasps do not make their appearance till they are wanted; till the plant has grown to a height to stand in need of support. Yet, it should be added, all slender and fragile climbing plants are not provided with tendrils; but some, as the ivy, adhere to a tree or wall.

This word "support" suggests to us a reflection upon a property of grasses, of corn,

and canes. The stems of these classes of plants are set, at certain intervals, with joints. These joints are not found in the trunks of trees, or in the solid stalks of plants. There may be other uses of these joints; but the fact is, and it appears to be at least one purpose designed by them, that they *corroborate* the stem; which, by its length or hollowness, would otherwise be too liable to break or bend: they may prevent, in dry situations, the too rapid exhaustion of the moisture.

*Grasses* are Nature's care. With these she clothes the earth; with these she sustains its inhabitants. Cattle feed upon their leaves; birds upon their smaller seeds; men upon the larger; for few readers need be told that the plants which, under cultivation, produce our bread-corn belong to this class. In those tribes which are more generally considered as grasses, their extraordinary means and powers of preservation and increase, their hardiness, their almost unconquerable disposition to spread, their faculties of reviviscence, coincide with the intention of nature concerning them. They thrive under a treatment by which other plants are destroyed. The more their leaves are consumed, the more their roots increase. The more they are trampled upon, the thicker they grow.

Many of the seemingly dry and dead grasses revive, and renew their verdure in the spring. In lofty mountains, where the summer heats are not sufficient to ripen the seeds, grasses abound, which are viviparous, and consequently able to propagate themselves without seeds. It is an observation, likewise, which has often been made, that herbivorous animals attach themselves to the leaves of grasses ; and, if at liberty in their pastures to range and choose, leave untouched the straws which support the flowers.<sup>1</sup> Yet the cereals, or bread-corn-producing grasses, are never found wild : they are annuals, and require tillage, and extensive employment of human labour. Thus, grass grows spontaneously for cattle, but food-plants by the cultivation of man.

The GENERAL properties of vegetable nature, or properties common to large portions of that kingdom, are almost all which the compass of our argument allows us to bring forward. It is impossible to follow plants into their several species. We may be allowed, however, to single out three or four of these species as worthy of a particular notice, either by some singular mechanism, or by some peculiar provision, or by both.

I. In Dr. Darwin's Botanic Garden (l. 395, note), is the following account of the *vallisneria*,

<sup>1</sup> Withering, Bot. Arr. vol. i. p. 28, ed. 2nd.

as it has been observed in the river Rhone. “They have roots at the bottom of the Rhone. The flowers of the *female plant* float on the surface of the water, and are furnished with an *elastic spiral stalk*, which extends or contracts as the water rises or falls ; this rise or fall, from the torrents which flow into the river, often amounting to many feet in a few hours. The flowers of the *male plant* are produced under water ; and as soon as the fecundating farina is mature, they separate themselves from the plant, rise to the surface, and are wafted by the air, or borne by the currents, to the female flowers.” Our attention in this narrative will be directed to two particulars ; first, to the mechanism, the “elastic spiral stalk,” which lengthens or contracts itself according as the water rises or falls ; secondly, to the provision which is made for bringing the male flower, which is produced *under* water, to the female flower which floats upon the surface.

II. My second example is the *cuscuta europaea*, which is a parasitical plant. After first vegetating in the earth, its shoot seeks a living stem of some other plant, into which it insinuates itself by means of fleshy tubercles. This attachment accomplished, the root dies : if it fail the whole plant perishes ; the short-lived

---

root being designed as a temporary expedient, to support the vegetation until its parasitical tendency is satisfied.

III. A better-known parasitical plant is the evergreen shrub, called the *mistletoe*, which is entirely without root at any period of its existence. What we have to remark in it is a singular instance of *compensation*. No art hath yet made these plants take root in the earth. Here therefore might seem to be a mortal defect in their constitution. Let us examine how this defect is made up to them. The seeds are endued with an adhesive quality so tenacious, that if they be rubbed upon the smooth bark of almost any tree, they will stick to it. And then what follows? Processes springing from these seeds, insinuate themselves into the woody substance of the tree; and the event is, that a mistletoe plant is produced next winter. The natural order of *Loranthacæ* furthermore exemplify this peculiarity, and illustrate this compensatory property of drawing nutriment from other sources, where the root is wanting.

IV. Another instance of the *compensatory* system is in the autumnal crocus, or meadow saffron (*colchicum autumnale*). I have pitied this poor plant a thousand times. Its blossom rises

out of the ground in the most forlorn condition possible ; without a sheath, a fence, a calyx, or even a leaf to protect it; and that, not in the spring, not to be visited by summer suns, but under all the disadvantages of the declining year. When we come, however, to look more closely into the structure of this plant, we find that, instead of its being neglected, Nature has gone out of her course to provide for its security, and to make up to it for all its defects. The seed-vessel, which in other plants is situated within the cup of the flower, or just beneath it, in this plant lies buried ten or twelve inches under ground within the bulbous root. The tube of the flower, which is seldom more than a few tenths of an inch long, in this plant extends down to the root. The styles in all cases reach the seed-vessel ; but it is in this, by an elongation unknown to any other plant. All these singularities contribute to one end. "As this plant blossoms late in the year, and probably would not have time to ripen its seeds before the access of winter, which would destroy them, Providence has so contrived its structure that this important office may be performed at a depth in the earth out of reach of the usual effects of frost."<sup>1</sup> That is to say, in the

<sup>1</sup> Withering, *ubi supra*, p. 360.

DIONÆA MUSCIPULA.

autumn nothing is done above ground but the business of impregnation; which is an affair between the antheræ and the stigmata, and is probably soon over. The maturation of the impregnated seed, which in other plants proceeds within a capsule exposed together with the rest of the flower to the open air, is here carried on, and during the whole winter, within the heart, as we may say of the earth, that is, "out of the reach of the usual effects of frost." But then a new difficulty presents itself. Seeds, though perfected, are known not to vegetate at this depth in the earth. Our seeds, therefore, though so safely lodged, would, after all, be lost to the purpose for which all seeds are intended. Lest this should be the case, "a second admirable provision is made to raise them above the surface when they are perfected, and to sow them at a proper distance:" viz. the germ grows up *in the spring*, upon a fruit-stalk, accompanied with leaves. The seeds now, in common with those of other plants, have the benefit of the summer, and are sown upon the surface. The order of vegetation externally is this:—The plant produces its flowers in September; its leaves and fruits in the spring following.

V. I give the account of the *dionaea muscipula*,

an extraordinary American plant, as some late authors have related it. Its leaves are jointed by a longitudinal rib, and furnished on their edges with two rows of strong prickles; their surfaces are also armed with a number of rather strong and sharp bristles. When these parts are touched by the legs of flies, the two lobes of the leaf instantly spring up, the rows of prickles lock themselves fast together, and squeeze the unwary animal to death. Here, under a new model, we recognize the ancient plan of nature, viz. the relation of parts and provisions to one another, to a common office, and to the utility of the organized body to which they belong. The rows of strong prickles, their position so as to interlock the joints of the leaves; and, what is more than the rest, that singular irritability of their surfaces, by which they close at a touch: all bear a contributory part in producing an effect, connected with the nutrition of the plant; for there seems to be little reason to doubt that it is carnivorous; actually digesting the prey which it thus entraps.

## CHAPTER XXI.

## THE ATMOSPHERE, WATER, HEAT AND LIGHT.

WE now take leave of the organic kingdom, and come to the consideration of agents which are universally essential to the very existence of life, whether in the animal or vegetable kingdom ; viz. air and water, heat and light.

We can never think of these without reflecting upon the number of distinct uses which are *consolidated* in the same substance. The *air* supplies the lungs, supports fire, conveys sound, furnishes a medium for the minute bodies which reflect light, diffuses smells, holds vapour, wafts ships, bears up birds. '*Ἐξ ὑδατος τα πάντα* : water, besides maintaining its own inhabitants, is the universal nourisher of plants, and through them, of terrestrial animals ; is the basis of their juices and fluids ; dilutes their food ; quenches their thirst ; floats their burdens. Heat is the great promoter of vegetation and life, and necessary to the support of both.

We might enlarge, to almost any length we

please, upon each of these uses ; but it appears to me almost sufficient to state them. The few remarks, which I judge it necessary to add, are as follow :—

I. There appears to be no necessity for an atmosphere's investing our globe except for its utility, yet it does invest it ; and we see how many, how various, and how important are the purposes which it answers to every order of animated beings, which are placed upon the terrestrial surface. I think that every one of these uses will be understood upon the first mention of them, except it be its connexion with *reflecting* light, which may be explained thus. If I had the power of seeing only by means of rays coming directly from the sun, whenever I turned my back upon the luminary, I should find myself in darkness. If I had the power of seeing by reflected light, yet by means only of light reflected from solid masses, these masses would shine indeed, and glisten, but it would be in the dark. The hemisphere, the sky, the world, could only be *illuminated*, as it is illuminated, by the light of the sun being from all sides, and in every direction, reflected to the eye, by particles, as numerous, as thickly scattered, and as widely diffused, as the air through which it passes.

Another general quality of the atmosphere is the power of holding vapour. The adjustment of this quality to our use is seen in the evaporation from the sea. In the sea, water and salt are mixed together most intimately; yet the atmosphere absorbs the water, and leaves the salt. Pure and fresh as drops of rain descend, they are collected from brine.

By evaporation, water is carried up into the air; by the converse of evaporation, it falls down upon the earth. And how does it fall? Not by the clouds being all at once re-converted into water, and descending like a sheet; not in rushing down in columns from a spout; but in moderate drops, as from a colander. Our watering-pots are made to imitate showers of rain. Yet, *à priori*, I should have thought either of the two former methods more likely to have taken place than the last.

By respiration, putrefaction, combustion, air is rendered unfit for the support of animal life. By the constant operation of these corrupting principles, the whole atmosphere, if there were no restoring causes, would come at length to be deprived of its necessary degree of purity. Many of these causes have been discovered, and their efficacy ascertained by experiment. And so far as the discovery has proceeded, it opens to

us a beautiful and a wonderful economy. *Vegetation* proves to be one of them. Plants require that which is deleterious to animals: the former absorb carbonic acid, and after decomposing it, yield oxygen for the use of the latter: other injurious gases are likewise resolved into their elements in various ways, to be again rendered available for new combinations. The remarkable law by which the diffusion of gases is regulated, is a striking proof of design in accomplishing a result on which the perpetuation of life depends. If gases were simply subject to the law of gravitation, the heavy gases would be found near the surface of the earth and the lighter in the higher regions. This would cause a mechanical separation of the lighter from the heavier gases, and would be fatal to animal life. Can we not see design in the law of diffusion which renders the law of gravitation partly inoperative, and causes the atmosphere to retain uniformly the same constituents in the same proportions? These agencies are further aided by constant and changing currents of air, and sometimes by tempests and hurricanes. Nothing can be of greater importance to the living creation than the salubrity of the atmosphere. It ought to reconcile us therefore to these agitations of the elements of which we sometimes

deplore the consequences, to know, that they tend powerfully to restore to the air that purity, which so many causes are constantly impairing.

II. In *Water*, what ought not a little to be admired, are those negative qualities which constitute its *purity*. Had it been vinous, or oleaginous, or acid ; had the sea been filled, or the rivers flowed, with wine or milk ; fish, constituted as they are, must have died ; plants, constituted as they are, would have withered ; the lives of animals which feed upon plants must have perished. Its very *insipidity*, which is one of those negative qualities, renders it the best of all menstrua. Having no taste of its own, it becomes the sincere vehicle of every other. Had there been a taste in water, be it what it might, it would have infected everything we ate or drank with an importunate repetition of the same flavour.

Another thing in this fluid, not less to be admired, is the constant *round* which it travels ; and by which, without suffering either adulteration or waste, it is continually offering itself to the wants of the habitable globe. From the sea are exhaled those vapours which form the clouds ; these clouds descend in showers, which, penetrating into the crevices of the hills, supply

springs; which springs flow in little streams into the valleys; and there, uniting, become rivers; which rivers, in return, feed the ocean. So there is an incessant circulation of the same fluid; and not more or less now than there was at the creation. A particle of water takes its departure from the surface of the sea, in order to fulfil certain important offices to the earth; and, having executed the service which was assigned to it, returns to the bosom which it left.

And here we may pause for a moment to notice the remarkable circumstance that, although water becomes heavier as it becomes colder, nearly to the point of freezing, when actually frozen, or converted into ice, it becomes lighter than the surrounding water. The result of this has a special importance; for, if ice were to sink to the bottom of our lakes and ponds, the summer's sun could scarcely thaw it. Moreover, by the expansion of water at a certain degree of cold, the winter frosts prepare the ground for future vegetation.

Some have thought that we have too much water upon the globe, the sea occupying above two thirds of its whole surface. But the expanse of ocean, immense as it is, may be no more than sufficient to fertilize the earth. Or,

independently of this reason, I know not why the sea may not have as good a right to its place as the land. It may proportionably support as many inhabitants; minister to as large an aggregate of enjoyment. The land only affords a habitable surface; the sea is habitable to a great depth.

The influence of *Heat* is universal. Without it neither animal nor vegetable life could exist, and numerous are the expedients we adopt to generate and economize it. But the great source of heat, as of light, is the sun. One great office indeed of heat in the economy of nature is keeping things in a state of solution, that is to say, in a state of fluidity. Were it not for the presence of heat, or of a certain degree of it, all fluids would be frozen. The ocean itself would be a quarry of ice; universal nature stiff and dead.

We see, therefore, that these things bear not only a strict relation to the constitution of organized bodies, but a relation to each other. Water could not perform its office to the earth without air; nor exist, as water, without heat.

It is altogether superfluous to expatiate upon the use of light. No man disputes it. The

observations, therefore, which I shall offer on this subject need be but few.

Light, which is propagated by undulations of a medium called ether which fills all space, travels from the sun at the rate of about twelve millions of miles in a minute.

It is impossible for the human mind to imagine to itself anything so wonderful as light. A drop of tallow, expended in the wick of a farthing candle, shall cause vibrations of the ether that will be perceived half a mile away by the eye. A stone thrown into a pond will create ripples that extend a long distance before they disappear. But the undulations in the ether which are excited by a light-giving body can hardly be said to disappear anywhere. They stretch out on all sides into the infinite. The waves, for instance, which have been set up in the ether by the most distant fixed stars, reach our eyes after being on the way for thousands of years.

We see something of design too in the varied colours which are produced by the waves of light not being all of the same length. This is of infinite use for us for the distinguishing of objects; and adds much to the beauty of the earth, while it augments the stock of our innocent pleasures.

## CHAPTER XXII.

## ASTRONOMY.

My opinion of Astronomy has always been, that it is *not* the best medium through which to prove the agency of an intelligent Creator; but that, this being proved, it shows, beyond all other sciences, the magnificence of His operations. The mind which is once convinced, it raises to sublimer views of the Deity than any other subject affords; but it is not so well adapted, as some other subjects are, to the purpose of argument. We are destitute of the means of sufficiently examining the constitution of the heavenly bodies. The very simplicity of their appearance is against them. We see nothing but bright points, luminous circles, or the phases of spheres reflecting the light which falls upon them. Now we deduce design from relation, aptitude, and correspondence of *parts*. Some degree, therefore, of *complexity* is necessary to render a subject fit for this species of argument.

---

The motions of the heavenly bodies are carried on without any sensible intermediate apparatus ; whereby we are cut off from one principal ground of argumentation, analogy. We have nothing wherewith to compare them ; no invention, no discovery, no operation or resource of art, which in this respect resembles them. Even those things which are made to imitate and represent them, such as orreries, planetaria, celestial globes, &c., bear no affinity to them, in the cause and principle by which their motions are actuated.

Our ignorance, moreover, of the *sensitive* natures by which other planets may be inhabited, necessarily keeps from us the knowledge of numberless utilities, relations, and subserviences, which we perceive upon our own globe.

After all ; the real subject of admiration is, that we understand so much of astronomy as we do. That an animal confined to the surface of one of the planets ; bearing a less proportion to it than the smallest microscopic insect does to the plant it lives upon ; that this little, busy, inquisitive creature, by the use of senses which were given to it for its domestic necessities, and by means of the assistants of those senses which it has had the art to procure, should have been enabled to observe the whole system of worlds to

which its own belongs ; the changes of place of the immense globes which compose it ; and with such accuracy, as to mark out, beforehand, the situation in the heavens in which they will be found at any future point of time ; and that these bodies, after sailing through regions of void and trackless space, should arrive at the place where they were expected, not within a minute, but within a few seconds of a minute, of the time prefixed and predicted ; all this is wonderful, whether we refer our admiration to the constancy of the heavenly motions themselves, or to the perspicacity and precision with which they have been noticed by mankind. Nor is this the whole, nor indeed the chief part, of what astronomy teaches. By bringing reason to bear upon observation (the acutest reasoning upon the exactest observation), the astronomer has been able, out of the “mystic dance,” and the seeming confusion under which the motions of the heavenly bodies present themselves to the eye of a mere gazer upon the skies, to elicit their order and their real paths.

Our knowledge therefore of astronomy is admirable, though imperfect ; and, amidst the confessed desiderata and desideranda which impede our investigation of the wisdom of the Deity, in these the grandest of His works, there

---

are to be found, in the phenomena, ascertained circumstances and laws, sufficient to indicate an intellectual agency in three of its principal operations, viz. in choosing, in determining, in regulating; in *choosing*, out of a boundless variety of suppositions which were equally possible, that which is beneficial; in *determining*, what, left to itself, had a thousand chances against convenience, for one in its favour; in *regulating* subjects, as to quantity and degree, which, by their nature, were unlimited with respect to either. It will be our business to offer, under each of these heads, a few instances, such as best admit of a popular explication.

I. Amongst proofs of choice, one is, fixing the source of light and heat in the *centre* of our system. The sun is ignited and luminous; the planets which move round him, cold and dark. There seems to be no antecedent necessity for this order. The sun might have been an opaque mass; some one, or two, or more, or any, or all the planets, globes of fire. There is nothing in the nature of the heavenly bodies which requires that those which are relatively stationary should be on fire, that those which move around them should be cold; for this order does not obtain between the primary planets and their secondaries, which are all opaque. When we consider,

---

therefore, that the sun is one ; that the planets going round it are numerous ; that it is indifferent to their nature, which are luminous and which are opaque ; and also, in what order, with respect to each other, these two kinds of bodies are disposed ; we may judge of the improbability of the present arrangement taking place by chance.

The preference of the present to any other mode of distributing luminous and opaque bodies I take to be evident. It requires more astronomy than I am able to lay before the reader to show, in its particulars, what would be the effect to the system, of a dark body at the centre, and of one of the planets being luminous : but I think it manifest, without either plates or calculation, first, that supposing the necessary proportion of magnitude between the central and the revolving bodies to be preserved, the ignited planet would be insufficient to illuminate and warm the rest of the system, although such light and heat as it distributed were imparted to the other planets.<sup>1</sup>

II. The conclusion to be drawn from geological investigation of the earth's crust is, that it was originally fluid and in a state of ignition ; and

<sup>1</sup> Some of Paley's arguments are here omitted as being inconsistent with the present state of science, and of those which are retained many must be considered as much modified by the Nebular Hypothesis.

that it gradually cooled sufficiently to support vegetation and the lowest forms of animal life, the vapour being condensed into water which, in course of time, collected on the surface. Therefore we may conceive the present face of the earth to have originated from the revolution of a sphere, the fluid and solid parts separating, as the surface cooled and became quiescent. Here then comes in the *moderating* hand of the Creator. If the water had exceeded its present proportion, even but by a trifling quantity compared with the whole globe, all the land would have been covered : had there been much less than there is, there would not have been enough to fertilize the continent. Had the exsiccation been progressive, such as we may suppose to have been produced by an evaporating heat, how came it to stop at the point at which we see it ? Why did it not stop sooner ? Why at all ? The mandate of the Deity will account for this ; nothing else will.

III. OF CENTRIPETAL FORCES. By virtue of the simplest law that can be imagined, viz. that a body *continues* in the state in which it is, whether of motion or rest ; and if in motion, goes on in the line in which it was proceeding, and with the same velocity, *unless* there be some cause for change: by virtue, I say, of

---

this law, it comes to pass (what may appear to be a strange consequence), that cases arise, in which attraction, incessantly drawing a body towards a centre, never brings, nor ever will bring, the body to that centre, but keep it in eternal circulation round it. If it were possible to fire off a cannon-ball with a velocity of five miles in a second, and the resistance of the air could be taken away, the cannon-ball would for ever wheel round the earth, instead of falling down upon it. This is the principle which sustains the heavenly motions. The Deity, having appointed this law to matter (than which, as we have said before, no law could be more simple), has turned it to a wonderful account in constructing planetary systems.

The actuating cause in these systems, is an attraction which all bodies have upon one another, and which varies reciprocally as the square of the distance; that is, at double the distance, has a quarter of the force; at half the distance, four times the strength; and so on. Now, concerning this law of variation, we have three things to observe: First; that attraction, for anything we know about it, was just as capable of one law of variation as of another: Secondly; that out of an infinite number of possible laws, those which were admissible for the purpose of

---

supporting the heavenly motions lay within certain narrow limits : Thirdly ; that of the admissible laws, or those which come within the limits prescribed, the law that actually prevails is the most beneficial. So far as these propositions can be made out, we may be said, I think, to prove *choice* and *regulation* : choice, out of boundless variety ; and regulation, of that which, by its own nature, was, in respect of the property regulated, indifferent and indefinite.

I. First then, attraction, for anything we know about it, might have been originally indifferent to all laws of variation depending upon change of distance, i.e. just as susceptible of one law as of another. It might have been the same at all distances ; it might have increased as the distance increased : or it might have diminished with the increase of the distance, yet in ten thousand different proportions from the present ; it might have followed no stated law at all. If attraction be what Cotes, with many other Newtonians, thought it to be, a primordial property of matter, not dependent upon, or traceable to, any other material cause ; then, by the very nature and definition of a primordial property, it stood indifferent to all laws. If it be the agency of something immaterial, then also, for anything we know of it, it was

indifferent to all laws. If the revolution of bodies round a centre depend upon vortices, neither are these limited to one law more than another.

II. Our second proposition is, that whilst the possible laws of variation were infinite, the *admissible* laws, or the laws compatible with the preservation of the system, lie within narrow limits. If the attracting force had varied according to any *direct* law of the distance, let it have been what it would, great destruction and confusion would have taken place. The direct simple proportion of the distance would, it is true, have produced an ellipse: but the perturbing forces would have acted with so much advantage, as to be continually changing the dimensions of the ellipse, in a manner inconsistent with our terrestrial creation. For instance; if the planet Saturn, so large and so remote, had attracted the earth, both in proportion to the quantity of matter contained in it, which it does; and also in any proportion to its distance, i. e. if it had pulled the harder for being the further off (instead of the reverse of it), it would have dragged out of its course the globe which we inhabit, and have perplexed its motions, to a degree incompatible with our security, our enjoyments, and probably our ex-

istence. Of the *inverse* laws, if the centripetal force had changed as the cube of the distance, or in any higher proportion, that is (for I speak to the unlearned), if, at double the distance, the attractive force had been diminished to an eighth part, or to less than that, the consequence would have been that the planets, if they once began to approach the sun, would have fallen into his body ; if they once, though by ever so little, increased their distance from the centre, would for ever have receded from it. The laws therefore of attraction, by which a system of revolving bodies could be upholden in their motions, lie within narrow limits, compared with the possible laws. I much underrate the restriction, when I say that, in a scale of a mile, they are confined to an inch. All direct ratios of the distance are excluded, on account of danger from perturbing forces ; all reciprocal ratios, except what lie beneath the cube of the distance, by the demonstrable consequence, that every the least change of distance would, under the operation of such laws, have been fatal to the repose and order of the system. We do not know, that is, we seldom reflect, how interested we are in this matter. Small irregularities may be endured ; but changes within these limits being allowed for,

the permanency of our ellipse is a question of life and death to our whole sensitive world.

III. That the subsisting law of attraction falls within the limits which utility requires, when these limits bear so small a proportion to the range of possibilities upon which chance might equally have cast it, is not, with any appearance of reason, to be accounted for by any other cause than a regulation proceeding from a designing mind. But our next proposition carries the matter somewhat further. We say, in the third place, that out of the different laws which lie within the limits of admissible laws, the *best* is made choice of; that there are advantages in this particular law which cannot be demonstrated to belong to any other law; and, concerning some of which, it can be demonstrated that they do not belong to any other.

1. Whilst this law prevails between each particle of matter, the *united* attraction of a sphere, composed of that matter, observes the same law. This property of the law is necessary, to render it applicable to a system composed of spheres, but it is a property which belongs to no other law of attraction that is admissible. The law of variation of the united attraction is in no other case the same as the law of attraction of each particle, one case

---

excepted, and that is of the attraction varying directly as the distance; the inconveniency of which law, in other respects, we have already noticed.

We may follow this regulation somewhat further, and still more strikingly perceive that it proceeded from a designing mind. A law both admissible and convenient was requisite. In what way is the law of the attracting globes obtained? Astronomical observations, and terrestrial experiments, show that the attraction of the globes of the system is made up of the attraction of their parts; the attraction of each globe being compounded of the attractions of its parts. Now the admissible and convenient law which exists, could not be obtained in a system of bodies gravitating by the united gravitation of their parts, unless each particle of matter were attracted by a force varying by one particular law, viz. varying inversely as the square of the distance; for, if the action of the particles be according to any other law whatever, the admissible and convenient law which is adopted could not be obtained. Here then are clearly shown regulation and design. A law both admissible and convenient was to be obtained: the mode chosen for obtaining that law was by making *each* particle of matter

act. After this choice was made, then further attention was to be given to each particle of matter, and one, and one only particular law of action to be assigned to it. No other law would have answered the purpose intended.

2. All systems must be liable to *perturbations*. And therefore, to guard against these perturbations, or rather to guard against their running to destructive lengths, is perhaps the strongest evidence of care and foresight that can be given. Now we are able to demonstrate of our law of attraction, what can be demonstrated of no other, and what qualifies the dangers which arise from cross but unavoidable influences, that the action of the parts of our system upon one another will not cause permanently increasing irregularities, but merely periodical or vibratory ones; that is, they will come to a limit, and then go back again. This we can demonstrate only of a system, in which the following properties concur, viz. that the force shall be inversely as the square of the distance; the masses of the revolving bodies small, compared with that of the body at the centre; the orbits not much inclined to one another; and their eccentricity little. In such a system the grand points are secure. The mean distances and periodic times, upon which

---

depend our temperature and the regularity of our year, are constant. The eccentricities, it is true, will still vary, but so slowly, and to so small an extent, as to produce no inconveniency from fluctuation of temperature and season. The same as to the obliquity of the planes of the orbits. For instance, the inclination of the ecliptic to the equator will never change above two degrees (out of ninety), and that will require many thousand years in performing.

It has been rightly also remarked, that if the great planets, Jupiter and Saturn, had moved in lower spheres, their influences would have had much more effect, as to disturbing the planetary motions, than they now have. While they revolve at so great distances from the rest, they act almost equally on the sun and on the inferior planets; which has nearly the same consequence as not acting at all upon either.

If it be said that the planets might have been sent round the sun in exact circles, in which case, no change of distance from the centre taking place, the law of variation of the attracting power would have never come in question, one law would have served as well as another; an answer to the scheme may be drawn from the consideration of these same perturbing forces. The system retaining in

other respects its present constitution, though the planets had been at first sent round in exact circular orbits, they could not have kept them: and if the law of attraction had not been what it is, or at least, if the prevailing law had transgressed the limits above assigned, every departure would have been fatal: the planet once drawn, as drawn it necessarily must have been, out of its course, would have wandered in endless error.

IV. What we have seen in the law of the centripetal force, viz. a choice guided by views of utility, and a choice of one law out of thousands which might equally have taken place, we see no less in the *figures* of the planetary orbits. It was not enough to fix the law of the centripetal force, though by the wisest choice; for, even under that law, it was still competent to the planets to have moved in paths possessing so great a degree of eccentricity, as in the course of every revolution, to be brought very near to the sun, and carried away to immense distances from him. The comets actually move in orbits of this sort; and had the planets done so, instead of going round in orbits nearly circular, the change from one extremity of temperature to another must, in ours at least, have destroyed every animal and

plant upon its surface. Now, the distance from the centre at which a planet sets off, and the absolute force of attraction at that distance being fixed, the figure of his orbit, its being a circle, or nearer to, or further off from a circle, viz. a rounder or a longer oval, depends upon two things, the velocity with which, and the direction in which, the planet is projected. And these, in order to produce a right result, must be both brought within certain narrow limits. One, and only one, velocity, united with one, and only one, direction, will produce a perfect circle. And the velocity must be near to this velocity, and the direction also near to this direction, to produce orbits, such as the planetary orbits are, nearly circular; that is, ellipses with small eccentricities. The velocity and the direction must *both* be right. If the velocity be wrong, no direction will cure the error; if the direction be in any considerable degree oblique, no velocity will produce the orbit required. Take for example the attraction of gravity at the surface of the earth. The force of that attraction being what it is out of all the degrees of velocity, swift and slow, with which a ball might be shot off, none would answer the purpose of which we are speaking, but what was nearly that of five miles

in a second. If it were less than that, the body would not get round at all, but would come to the ground; if it were in any considerable degree more than that, the body would take one of those eccentric courses, those long ellipses, of which we have noticed the inconveniency. If the velocity reached the rate of seven miles in a second, or went beyond that, the ball would fly off from the earth, and never be heard of more. In like manner with respect to the *direction*; out of the innumerable angles in which the ball might be sent off (I mean angles formed with a line drawn to the centre), none would serve but what was nearly a right one: out of the various directions in which the cannon might be pointed, upwards and downwards, every one would fail, but what was exactly or nearly horizontal. The same thing holds true of the planets: of our own amongst the rest. We are entitled therefore to ask, and to urge the question, Why did the projectile velocity and projectile direction of the earth happen to be nearly those which would retain it in a *circular* form? Why not one of the infinite number of velocities, one of the infinite number of directions, which would have made it approach much nearer to, or recede much further from, the sun?

In regard to the origin of our planetary

---

system and the relation of the planets to the sun, Maclaurin has made the following apposite remarks :—

“ If we suppose the matter of the system to be accumulated in the centre by its gravity, *no* mechanical principles, with the assistance of this power of gravity, could separate the vast mass into such parts as the sun and planets ; and, after carrying them to their different distances, project them in their several directions, preserving still the quality of action and reaction, or the state of the centre of gravity of the system. Such an exquisite structure of things could only arise from the contrivance and powerful influences of an intelligent, free and most potent agent. The same powers, therefore, which at present govern the material universe, and conduct its various motions, are *very different* from those, which were necessary to have produced it from nothing, or to have disposed it in the admirable form in which it now proceeds.”<sup>1</sup>

To conclude : In astronomy, the great thing is to raise the imagination to the subject, and that oftentimes in opposition to the impression made upon the senses. An illusion, for example, must be gotten over, arising from the distance

<sup>1</sup> Maclaurin’s Account of Newton’s Philosophy, p. 407.

at which we view the heavenly bodies, viz. the apparent *slowness* of their motions. The moon shall take a long time in getting half a yard from a star which it touched. A motion so deliberate we may think easily guided. But what is the fact? The moon, in fact, is, all this while, driving through the heavens, at the rate of considerably more than two thousand miles in an hour; which is about double of that, with which a ball is shot off from the mouth of a cannon. Yet is this prodigious rapidity as much under government, as if our satellite proceeded ever so slowly, or were conducted in her course inch by inch. It is also difficult to bring the imagination to conceive (what yet, to judge tolerably of the matter, it is necessary to conceive) how *loose*, if we may so express it, the heavenly bodies are. Enormous globes, held by nothing, confined by nothing, are turned into free and boundless space, each to seek its course by the virtue of an invisible principle; but a principle, one, common, and the same in all; and ascertainable. To preserve such bodies from being lost, from running together in heaps, from hindering and distracting one another's motions, in a degree inconsistent with any continuing order; *h. e.* to cause them to form planetary systems, systems that, whev.

---

formed, can be upheld, and, most especially, systems accommodated to the organized and sensitive natures which the planets sustain, as we know to be the case, where alone we can know what the case is, upon our earth : all this requires an intelligent interposition, because it can be demonstrated concerning it, that it requires an adjustment of force, distance, direction, and velocity, out of the reach of chance to have produced ; an adjustment, in its view to utility, similar to that which we see in ten thousand subjects of nature which are nearer to us, but in power, and in extent of space through which that power is exerted, stupendous.

It is thus we are brought to the conclusion that the grand and universal law of gravitation cannot be reasonably supposed to have arisen from some felicitous accident, or to have continued without purpose or design to govern the force which holds the material universe together, and is essential to its permanence and well-being. The evidences of selection, adaptation, and arrangement seem to show irresistibly that attraction itself is the offspring and instrument of a superior agent ; that there is a power above the highest of the powers of nature ; a will which originates and circumscribes the operations of the most extensive.

## CHAPTER XXIII.

### OF THE PERSONALITY OF THE DEITY.

CONTRIVANCE, if established, appears to me to prove everything which we wish to prove. Amongst other things, it proves the *personality* of the Deity, as distinguished from what is sometimes called nature, sometimes called a principle: which terms, in the mouths of those who use them philosophically, seem to be intended to admit and to express an efficacy, but to exclude and to deny a personal agent. Now that which can contrive, which can design, must be a person. These capacities constitute personality, for they imply consciousness and thought. They require that which can perceive an end or purpose; as well as the power of providing means, and of directing them to their end.<sup>1</sup> They require a centre in which perceptions unite and from which volitions flow; which is mind. The acts of a mind

<sup>1</sup> Priestley's Letters to a Philosophical Unbeliever, p. 153, ed. 2.

prove the existence of a mind ; and in whatever a mind resides, is a person. The seat of intellect is a person. We have no authority to limit the properties of mind to any particular corporeal form, or to any particular circumscription of space. These properties subsist in created nature under a great variety of sensible forms. Also every animated being has its *sensorium*, that is, a certain portion of space, within which perception and volition are exerted. This sphere may be enlarged to an indefinite extent; may comprehend the universe ; and, being so imagined, may serve to furnish us with as good a notion as we are capable of forming, of the *immensity* of the Divine Nature—i. e. of a Being, infinite, as well in essence as in power ; yet nevertheless a person.

“ No man hath seen God at any time.” And this, I believe, makes the great difficulty. Now it is a difficulty which chiefly arises from our not duly estimating the state of our faculties. The Deity, it is true, is the object of none of our senses : but reflect what limited capacities animal senses are. Many animals seem to have but one sense, or perhaps two at the most ; touch and taste. Ought such an animal to conclude against the existence of odours, sounds, and colours ? To another species is given the

sense of smelling. This is an advance in the knowledge of the power and properties of nature: but, if this favoured animal should infer from its superiority over the class last described, that it perceived everything which was perceptible in nature, it is known to us, though perhaps not suspected by the animal itself, that it proceeded upon a false and presumptuous estimate of its faculties. To another is added the sense of hearing; which lets in a class of sensations entirely unconceived by the animal before spoken of; not only distinct, but remote from any which *it* had ever experienced, and greatly superior to them. Yet this last animal has no more ground for believing that its senses comprehend all things, and all properties of things, which exist, than might have been claimed by the tribes of animals beneath it; for we know that it is still possible to possess another sense, that of sight, which shall disclose to the percipient a new world. This fifth sense makes the animal what the human animal is: but to infer that possibility stops here; that either this fifth sense is the last sense, or that the five comprehend all existence, is just as unwarrantable a conclusion, as that which might have been made by any of the different species which possessed fewer, or

even by that, if such there be, which possessed only one. The conclusion of the one-sense animal, and the conclusion of the five-sense animal, stand upon the same authority. There may be more and other senses than those which we have. There may be senses suited to the perception of the powers, properties, and substance of spirits. These may belong to higher orders of rational agents: for there is not the smallest reason for supposing that we are the highest, or that the scale of creation stops with us.

The great *energies* of nature are known to us only by their effects. The substances which produce them are as much concealed from our senses as the Divine Essence itself. *Gravitation* though constantly present, though constantly exerting its influence, though everywhere around us, near us, and within us; though diffused throughout all space, and penetrating the texture of all bodies with which we are acquainted, depends, if upon a fluid, upon a fluid which, though both powerful and universal in its operation, is no object of sense to us; if upon any other kind of substance or action, upon a substance and action from which *we* receive no distinguishable impressions. Is it then to be wondered at, that it should, in some measure, be the same with the Divine Nature?

Of this however we are certain, that whatever the Deity be, neither the *universe*, nor any part of it which we see, can be He. The universe itself is merely a collective name : its parts are all which are real; or which are *things*. Now inert matter is out of the question : and organized substances include marks of contrivance. But whatever includes marks of contrivance—whatever, in its constitution, testifies design, necessarily carries us to something beyond itself, to some other being, to a designer prior to, and out of, itself. No animal, for instance, can have contrived its own limbs and senses ; can have been the author to itself of the design with which they were constructed. That supposition involves all the absurdity of self-creation, i. e., of acting without existing. Nothing can be God, which is ordered by a wisdom and a will which itself is void of ; which is indebted for any of its properties to contrivance *ab extra*. The *not* having that in his nature which requires the exertion of another prior being (which property is sometimes called self-sufficiency, and sometimes self-comprehension), appertains to the Deity, as his essential distinction, and removes his nature from that of all things which we see. Which consideration contains the answer to a question that has some-

times been asked, namely, Why, since something or other must have existed from eternity, may not the present universe be that something? The contrivance perceived in it proves that to be impossible. Nothing contrived can, in a strict and proper sense, be eternal, forasmuch as the contriver must have existed before the contrivance.

Wherever we see marks of contrivance, we are led for its cause to an *intelligent* author. And this transition of the understanding is founded upon uniform experience. We see intelligence constantly contriving, that is, we see intelligence constantly producing effects, marked and distinguished by certain properties; not certain particular properties, but by a kind and class of properties, such as relation to an end, relation of parts to one another, and to a common purpose. We see, wherever we are witnesses to the actual formation of things, nothing except intelligence producing effects so marked and distinguished. Furnished with this experience, we view the productions of nature. We observe *them* also marked and distinguished in the same manner. We wish to account for their origin. Our experience suggests a cause perfectly adequate to this account. No experience, no single instance or example can be offered in favour of any other.

In this cause therefore we ought to rest; in this cause the common sense of mankind has, in fact, rested, because it agrees with that, which, in all cases, is the foundation of knowledge,—the undeviating course of their experience. The reasoning is the same as that by which we conclude any ancient appearances to have been the effects of volcanoes or inundations, namely, because they resemble the effects which fire and water produce before our eyes; and because we have never known these effects to result from any other operation. And this resemblance may subsist in so many circumstances, as not to leave us under the smallest doubt in forming our opinion. Men are not deceived by this reasoning: for whenever it happens, as it sometimes does happen, that the truth comes to be known by direct information, it turns out to be what was expected. In like manner, and upon the same foundation (which in truth is that of experience), we conclude that the works of nature proceed from intelligence and design, because, in the properties of relation to a purpose, subser-  
vency to a use, they resemble what intelligence and design are constantly producing, and what nothing except intelligence and design ever produce at all. Of every argument, which would raise a question as to the safety of this reasoning,

it may be observed, that if such argument be listened to, it leads to the inference, not only that the present order of nature is insufficient to prove the existence of an intelligent Creator, but that no imaginable order would be sufficient to prove it ; that *no* contrivance, were it ever so mechanical, ever so precise, ever so clear, ever so perfectly like those which we ourselves employ, would support this conclusion. A doctrine to which I conceive no sound mind can assent.

The force, however, of the reasoning is sometimes sunk by our taking up with mere names. We have already noticed,<sup>2</sup> and we must here notice again, the misapplication of the term “ law,” and the mistake concerning the idea which that term expresses in physics, whenever such idea is made to take the place of power, and still more of an intelligent power, and as such, is assigned for the cause of anything, or of any property of anything that exists. This is what we are secretly apt to do, when we speak of organized bodies (plants for instance, or animals), owing their production, their form, their growth, their qualities, their beauty, their use, to any law or laws of nature ; and when we are contented to sit down with that answer to our inquiries concerning them. I say once more, that it is a

<sup>2</sup> Chap. I. sect. vii.

perversion of language to assign any law as the efficient operative cause of anything. A law presupposes an agent, for it is only the mode according to which an agent proceeds ; it implies a power, for it is the order according to which that power acts. Without this agent, without this power, which are both distinct from itself, the “law” does nothing ; is nothing.

What has been said concerning “law” holds true of *mechanism*. Mechanism is not itself power. Mechanism, without power, can do nothing. Let a watch be contrived and constructed ever so ingeniously ; be its parts ever so many, ever so complicated, ever so finely wrought or artificially put together, it cannot *go* without a weight or spring, i. e., without a force independent of, and ulterior to, its mechanism. The spring acting at the centre will produce different motions and different results, according to the variety of the intermediate mechanism. One and the self-same spring, acting in one and the same manner, viz., by simply expanding itself, may be the cause of a hundred different and all useful movements, if a hundred different and well-devised sets of wheels be placed between it and the final effect ; e. g. may point out the hour of the day, the day of the month, the age of the moon, the position of the planets, the

cycle of the years, and many other serviceable notices; and these movements may fulfil their purposes with more or less perfection, according as the mechanism is better or worse contrived, or better or worse executed, or in a better or worse state of repair; *but in all cases it is necessary that the spring act at the centre.* The course of our reasoning upon such a subject would be this. By inspecting the watch, even when standing still, we get a proof of contrivance, and of a contriving mind having been employed about it. In the form and obvious relation of its parts, we see enough to convince us of this. If we pull the works in pieces, for the purpose of a closer examination, we are still more fully convinced. But when we see the watch *going*, we see proof of another point, viz., that there is a power somewhere, and somehow or other, applied to it; a power in action;—that there is more in the subject than the mere wheels of the machine;—that there is a secret spring, or a gravitating plummet;—in a word, that there is force and energy, as well as mechanism.

So then, the watch in motion establishes to the observer two conclusions: One, that thought, contrivance and design have been employed in the forming, proportioning and arranging of its parts; and that whoever or wherever he

be or were, such a contriver there is or was : The other, that force or power, distinct from mechanism, is at this present time acting upon it. If I saw a hand-mill even at rest, I should see contrivance ; but if I saw it grinding, I should be assured that a hand was at the windlass, though in another room. It is the same in nature. In the works of nature we trace mechanism ; and this alone proves contrivance : but living, active, moving, productive nature proves also the exertion of a power at the centre : for wherever the power resides may be denominated the centre.

The intervention and disposition of what are called "*second causes*" fall under the same observation. This disposition is or is not mechanism, according as we can or cannot trace it by our senses and means of examination. That is all the difference there is ; and it is a difference which respects our faculties, not the things themselves. Now where the order of second causes is mechanical, what is here said of mechanism strictly applies to it. But it would be always mechanism (natural chemistry, for instance, would be mechanism), if our senses were acute enough to descry it. Neither mechanism therefore in the works of nature, nor the intervention of what are called second causes

(for I think that they are the same thing), excuses the necessity of an agent distinct from both.

If, in tracing these causes, it be said, that we find certain general properties of matter which have nothing in them that bespeaks intelligence, I answer, that still the *managing* of these properties, the pointing, and directing them to the uses which we see made of them, demands intelligence in the highest degree. For example; suppose animal secretions to be elective attractions, and that such and such attractions universally belong to such and such substances; in all which there is no intellect concerned; still the choice and collocation of these substances, the fixing upon right substances, and disposing them in right places, must be an act of intelligence. What mischief would follow, were there a single transposition of the secretory organs; a single mistake in arranging the glands which compose them!

There may be many second causes, and many courses of second causes, one behind another, between what we observe of nature and the Deity: but there must be intelligence somewhere; there must be more in nature than what we see; and amongst the things unseen, there must be an intelligent, designing author. The

philosopher beholds with astonishment the production of things around him. Unconscious particles of matter take their stations, and severally range themselves in an order, so as to become collectively plants or animals, i. e. organized bodies, with parts bearing strict and evident relation to one another, and to the utility of the whole: and it should seem that these particles could not move in any other way than as they do; for they testify not the smallest sign of choice, or liberty, or discretion. There may be particular intelligent beings guiding these motions in each case: or they may be the result of trains of mechanical dispositions, fixed beforehand by an intelligent appointment, and kept in action by a power at the centre. But, in either case, there must be intelligence.

The minds of most men are fond of what they call a *principle*, and of the appearance of simplicity, in accounting for phenomena. Yet this principle, this simplicity, resides merely in the *name*; which name, after all, comprises perhaps under it a diversified, multifarious, or progressive operation, distinguishable into parts. The power in organized bodies of producing bodies like themselves, is one of these principles. Give a philosopher this, and he can get on. But he does not reflect what this mode of production,

this principle (if such he choose to call it) requires; how much it presupposes; what an apparatus of instruments, some of which are strictly mechanical, is necessary to its success; what a train it includes of operations and changes, one succeeding another, one related to another, one ministering to another; all advancing, by intermediate, and frequently, by sensible steps, to their ultimate result! Yet, because the whole of this complicated action is wrapped up in a single term, *generation*, we are to set it down as an elementary principle: and to suppose, that when we have resolved the things which we see into this principle, we have sufficiently accounted for their origin, without the necessity of a designing, intelligent Creator. The truth is, generation is not a principle, but a *process*. We might as well call the casting of metals a principle; we might, so far as appears to me, as well call spinning and weaving principles: and then, referring the texture of cloths, the fabric of muslins and calicoes, the patterns of diapers and damasks to these, as principles, pretend to dispense with intention, thought, and contrivance on the part of the artist; or to dispense, indeed, with the necessity of any artist at all, either in the manufacturing of the article, or in the fabrica-

tion of the machinery by which the manufacture was carried on.

And after all, how, or in what sense, is it true that animals produce their *like*? A butterfly, with a proboscis instead of a mouth, with four wings and six legs, produces a hairy caterpillar, with jaws and teeth and fourteen feet. A frog produces a tadpole. A black beetle, with gauze wings, and a crusty covering, produces a white, smooth, soft worm; an ephemeron fly, a cod-bait maggot. These, by a progress through different stages of life, and action, and enjoyment (and in each state provided with implements and organs appropriated to the temporary nature which they bear), arrive at last at the form and fashion of the parent animal. But all this is process, not principle; and proves, moreover, that the property of animated bodies, of producing their like, belongs to them, not as a primordial property, not by any blind necessity in the nature of things, but as the effect of economy, wisdom, and design; because the property itself assumes diversities, and submits to deviations dictated by intelligible utilities, and serving distinct purposes of animal happiness.

The opinion, which would consider “generation” as a *principle* in nature; and which

would assign this principle as the cause, or endeavour to satisfy our minds with such a cause, of the existence of organized bodies, is confuted, in my judgment, not only by every mark of contrivance discoverable in those bodies, for which it gives us no contriver, offers no account whatever; but also by the farther consideration, that things generated possess a clear relation to things *not* generated. If it were merely one part of a generated body bearing a relation to another part of the same body, as the mouth of an animal to the throat, the throat to the stomach, the stomach to the intestines, those to the recruiting of the blood, and by means of the blood, to the nourishment of the whole frame: or if it were only one generated body bearing relation to another generated body, as the sexes of the same species to each other, animals of prey to their prey, herbivorous and granivorous animals to the plants or seeds upon which they feed, it might be contended that the whole of this correspondence was attributable to generation, the common origin from which these substances proceeded. But what shall we say to agreements which exist between things generated and things *not generated*? Can it be doubted, was it ever doubted, but that the *lungs* of animals bear a

relation to the *air*, as a permanently elastic fluid? They act in it and by it; they cannot act without it. Now, if generation produced the animal, it did not produce the air: yet their properties correspond. The *eye* is made for *light*, and light for the eye. The eye would be of no use without light, and light would lose one of its chief uses without eyes; yet one is produced by generation; the other not. The *ear* depends upon *undulations* of air. Here are two sets of motions; first, of the pulses of the air; secondly, of the drum membrane and bones of the ear; sets of motions bearing an evident reference to each other: yet the one, and the apparatus for the one, produced by the intervention of generation; the other altogether independent of it.

If it be said, that the air, the light, the elements, the world itself, is *generated*; I answer, that I do not comprehend the proposition. If the term mean anything, similar to what it means when applied to plants or animals, the proposition is certainly without proof; and, I think, draws as near to absurdity as any proposition can do, which does not include a contradiction in its terms. I am at a loss to conceive, how the formation of the world can be compared to the generation of an animal. If the term

generation signify something quite different from what it signifies on ordinary occasions, it may, by the same latitude, signify anything. In which case, a word or phrase taken from the language of Otaheite, would convey as much theory concerning the origin of the universe, as it does to talk of its being generated.

We know a cause (intelligence) adequate to the appearances, which we wish to account for : we have this cause continually producing similar appearances : yet rejecting this cause, the sufficiency of which we know, and the action of which is constantly before our eyes, we are invited to resort to suppositions destitute of a single fact for their support, and confirmed by no analogy with which we are acquainted. Were it necessary to inquire into the *motives* of men's opinions, I mean their motives separate from their arguments, I should almost suspect, that, because the proof of a Deity drawn from the constitution of nature is not only popular but vulgar (which may arise from the cogency of the proof, and be indeed its highest recommendation), and because it is a species almost of *puerility* to take up with it ; for these reasons, minds, which are habitually in search of invention and originality, feel a resistless inclination to strike off into other solutions and other expositions. The truth

is, that many minds are not so indisposed to anything which can be offered to them, as they are to the *flatness* of being content with common reasons : and, what is most to be lamented, minds conscious of superiority are the most liable to this repugnancy.

The “suppositions” here alluded to all agree in one character ; they all endeavour to dispense with the necessity, in nature, of a particular, personal intelligence ; that is to say, with the exertion of an intending, contriving mind, in the structure and formation of the organized constitutions which the world contains. They would resolve all productions into *unconscious* energies, of a like kind, in that respect, with attraction, magnetism, electricity, &c., without anything further.

In this the old system of atheism and the new agree. And I much doubt whether the new schemes have advanced anything upon the old, or done more than changed the terms of the nomenclature. For instance, I could never see the difference between the antiquated system of atoms and Buffon’s organic molecules. This philosopher, having made a planet by knocking off from the sun a piece of melted glass, in consequence of the stroke of a comet ; and having set it in motion by the same stroke, both round

its own axis and the sun, finds his next difficulty to be, how to bring plants and animals upon it. In order to solve this difficulty, we are to suppose the universe replenished with particles endowed with life, but without organization or senses of their own; and endowed also with a tendency to marshal themselves into organized forms. The concourse of these particles, by virtue of this tendency, but without intelligence, will, or direction (for I do not find that any of these qualities are ascribed to them), has produced the living forms which we now see.

Very few of the conjectures, which philosophers hazard upon these subjects, have more of pretension in them, than the challenging you to show the direct impossibility of the hypothesis. In the present example, there seemed to be a positive objection to the whole scheme upon the very face of it; which was that, if the case were as here represented, *new* combinations ought to be perpetually taking place; new plants and animals, or organized bodies which were neither, ought to be starting up before our eyes every day. For this, however, our philosopher has an answer. Whilst so many forms of plants and animals are already in existence, and, consequently, so many "internal moulds," as he calls them, are prepared and at hand, the organic

particles run into these moulds, and are employed in supplying an accession of substance to them, as well for their growth as for their propagation. By which means things keep their ancient course. But, says the same philosopher, should any general loss or destruction of the present constitution of organized bodies take place, the particles, for want of “moulds” into which they might enter, would run into different combinations, and replenish the waste with new species of organized substances.

Is there any history to countenance this notion? Is it known, that any destruction has been so repaired? any desert thus re-peopled?

So far as I remember, the only natural appearance mentioned by our author, by way of fact whereon to build his hypothesis, is the formation of *worms* in the intestines of animals, which is here ascribed to the coalition of superabundant organic particles, floating about in the first passages; and which have combined themselves into these simple animal forms, for want of internal moulds, or of vacancies in those moulds, into which they might be received. The thing referred to is rather a species of facts, than a single fact; as some other cases may, with equal reason, be included under it. But to make it a fact at all, or in any sort applicable to the

question, we must begin with asserting an *equivocal* generation, contrary to analogy, and without necessity: contrary to an analogy which accompanies us to the very limits of our knowledge or inquiries; for wherever, either in plants or animals, we are able to examine the subject, we find procreation from a parent form: without necessity; for I apprehend that it is seldom difficult to suggest methods, by which the eggs, or spawn, or yet invisible rudiments of these vermin, may have obtained a passage into the cavities in which they are found.<sup>3</sup> Add to this, that their *constancy to their species*, which I believe, is as regular in these as in the other vermes, decides the question against our philosopher, if in truth any question remained upon the subject.

Lastly; these wonder-working instruments, these “internal moulds,” what are they after all? what, when examined, but a name without signification; unintelligible, if not self-contradictory! at the best, differing in nothing from the “essential forms” of the Greek philosophy?

<sup>3</sup> I trust I may be excused, for not citing, as another fact which is to confirm the hypothesis, a grave assertion of this writer, that the branches of trees upon which the stag feeds break out again in his horns. Such facts merit no discussion.

One short sentence of Buffon's work exhibits his scheme as follows : " When this nutritious and prolific matter, which is diffused throughout all nature, passes through the *internal mould* of an animal or vegetable, and finds a proper matrix, or receptacle, it gives rise to an animal or vegetable of the same species." Does any reader annex a meaning to the expression "internal mould," in this sentence ? Ought it then to be said, that though we have little notion of an internal mould, we have not much more of a designing mind ? The very contrary of this assertion is the truth. When we speak of an artificer or an architect, we talk of what is comprehensible to our understanding, and familiar to our experience. We use no other terms, than what refer us for their meaning to our consciousness and observation ; what express the constant objects of both ; whereas names, like that we have mentioned, refer us to nothing ; excited no idea ; convey a sound to the ear, but I think do no more.

Another system, which has lately been brought forward, and with much ingenuity, is that of *appetencies*. The principle, and the short account of the theory, is this : Pieces of soft, ductile matter, being endued with propensities or appetencies for particular actions, would, by

continual endeavours, carried on through a long series of generations, work themselves gradually into suitable forms; and at length acquire, though perhaps by obscure and almost imperceptible improvements, an organization fitted to the action which their respective propensities led them to exert. A piece of animated matter, for example, that was endued with a propensity to *fly*, though ever so shapeless, though no other we will suppose than a round ball, to begin with, would, in a course of ages, if not in a million of years, perhaps in a hundred millions of years (for our theorists, having eternity to dispose of, are never sparing in time), acquire *wings*. The same tendency to locomotion in an aquatic animal, or rather in an animated lump which might happen to be surrounded by water, would end in the production of *fins*: in a living substance, confined to the solid earth, would put out *legs* and *feet*; or, if it took a different turn, would break the body into ringlets, and conclude by *crawling* upon the ground.

Although I have introduced the mention of this theory into this place, I am unwilling to give to it the name of an *atheistic* scheme, for two reasons; first, because, so far as I am able to understand it, the original propensities, and the numberless varieties of them (so different in

this respect, from the laws of mechanical nature, which are few and simple), are in the plan itself attributed to the ordination and appointment of an intelligent and designing Creator: secondly, because, likewise, that large postulatum, which is all along assumed and presupposed, the faculty in living bodies of producing other bodies organized like themselves, seems to be referred to the same cause; at least is not attempted to be accounted for by any other. In one important respect, however, the theory before us coincides with atheistic systems, viz. in that, in the formation of plants and animals, in the structure and use of their parts, it does away final causes. Instead of the parts of a plant or animal, or the particular structure of the parts, having been intended for the action or the use to which we see them applied, according to this theory, they have themselves grown out of that action, sprung from that use. The theory therefore dispenses with that which we insist upon, the necessity, in each particular case, of an intelligent, designing mind, for the contriving and determining of the forms which organized bodies bear. Give our philosopher these appetencies; give him a portion of living irritable matter (a nerve, or the clipping of a nerve), to work upon; give also to his

incipient or progressive forms, the power, in every stage of their alteration, of propagating their like; and, if he is to be believed, he could replenish the world with all the vegetable and animal productions which we at present see in it.

The scheme under consideration is open to the same objection with other conjectures of a similar tendency, viz. a total defect of evidence. No changes, like those which the theory requires, have ever been observed. All the changes in Ovid's Metamorphoses might have been effected by these appetencies, if the theory were true: yet not an example, nor the pretence of an example, is offered of a single change being known to have taken place. Nor is the order of generation obedient to the principle upon which this theory is built. The mammæ of the male have not vanished by inusitation; *nec curtorum, per multa sœcula Judœorum propagini deest præputium.* It is easy to say, and it has been said, that the alterative process is too slow to be perceived; that it has been carried on through tracts of immeasurable time; and that the present order of things is the result of a gradation, of which no human record can trace the steps. It is easy to say this; and yet it is still true, that

the hypothesis remains destitute of satisfactory evidence.<sup>4</sup>

The *analogies* which have been alleged are of the following kind: The *bunch* of a camel is

GROUP OF CAMELS.

said to be no other than the effect of carrying burdens; a service in which the species has been employed from the most ancient times of the world. The first race, by the daily loading of the back, would probably find a small tumour

<sup>4</sup> The reader is referred to the "Introduction."

to be formed in the flesh of that part. The next progeny would bring this tumour into the world with them. The life to which they were destined would increase it. The cause which first generated the tubercle being continued, it would go on, through every succession, to augment its size, till it attained the form and the bulk under which it now appears. This may serve for one instance; another, and that also of the passive sort, is taken from certain species of birds. Birds of the *crane* kind, as the crane itself, the heron, bittern, stork, have, in general, their thighs bare of feathers. This privation is accounted for from the habit of wading in water, and from the effect of that element to check the growth of feathers upon these parts: in consequence of which, the health and development of the feathers declined through each generation of the animal; the tender down, exposed to cold and wetness, became weak, and thin, and rare, till the deterioration ended in the result, which we see, of absolute nakedness. I will mention a third instance, because it is drawn from an active habit, as the two last were from passive habits; and that is the *pouch* of the pelican. The description which naturalists give of this organ is as follows: "From the lower edges of the under chap-

hangs a bag, reaching from the whole length of the bill to the neck, which is said to be capable of containing fifteen quarts of water. This bag the bird has a power of wrinkling up

PELICANS.

into the hollow of the under-chap. When the bag is empty it is not seen; but when the bird has fished with success, it is incredible to what an extent it is often dilated. The first thing

the pelican does in fishing is to fill the bag; and then it returns to digest its burden at leisure. The bird preys upon the large fishes, and hides them by dozens in its pouch. When the bill is opened to its widest extent, a person may run his head into the bird's mouth; and conceal it in this monstrous pouch, thus adapted for very singular purposes." Now this extraordinary conformation is nothing more, say our philosophers, than the result of habit; not of the habit or effort of a single pelican, or of a single race of pelicans, but of a habit perpetuated through a long series of generations. The pelican soon found the conveniency of reserving in its mouth, when its appetite was glutted, the remainder of its prey, which is fish. The fulness, produced by this attempt, of course stretched the skin which lies between the underchaps, as being the most yielding part of the mouth. Every distension increased the cavity. The original bird, and many generations which succeeded him, might find difficulty enough in making the pouch answer this purpose; but future pelicans, entering upon life with a pouch derived from their progenitors, of considerable capacity, would more readily accelerate its advance to perfection, by frequently pressing down the sac with the

weight of fish which it might now be made to contain.

These, or of this kind, are the analogies relied upon. Now, in the first place, the instances themselves are unauthenticated by testimony; and in theory, to say the least of them, open to great objections. Who ever read of camels without bunches, or with bunches less than those with which they are at present usually formed? A bunch, not unlike the camel's, is found between the shoulders of the buffalo; of the origin of which it is impossible to give the account here given. In the second example; why should the application of water, which appears to promote and thicken the growth of feathers upon the bodies and breasts of geese and swans, and other water-fowls, have divested of this covering the thighs of cranes? The third instance, which appears to me as plausible as any that can be produced, has this against it, that it is a singularity restricted to the species; whereas, if it had its commencement in the cause and manner which have been assigned, the like conformation might be expected to take place in other birds which feed upon fish. How comes it to pass, that the pelican alone was the inventress, and her descendants the only inheritors, of this curious resource?

But it is the less necessary to controvert the instances themselves, as it is a straining of analogy beyond all limits of reason and credibility, to assert that birds, and beasts, and fish, with all their variety and complexity of organization, have been brought into their forms, and distinguished into their several kinds and natures, by the same process (even if that process could be demonstrated, or had it ever been actually noticed), as might seem to serve for the gradual generation of a camel's bunch, or a pelican's pouch.

The solution, when applied to the works of nature *generally*, is contradicted by many of the phenomena, and totally inadequate to others. The *ligaments* or strictures, by which the tendons are tied down at the angles of the joints, could by no possibility be formed by the motion or exercise of the tendons themselves; by any appetency exciting these parts into action; or by any tendency arising therefrom. The tendency is all the other way; the *conatus* in constant opposition to them. Length of time does not help the case at all, but the reverse. The *valves* also, in the blood-vessels, could never be formed in the manner which our theorist proposes. The blood, in its right and natural course, has no tendency to form them. When

obstructed or refluent, it has the contrary. These parts could not grow out of their use, though they had eternity to grow in.

The *senses* of animals appear to me altogether incapable of receiving the explanation of their origin which this theory affords. Including under the word “sense” the organ and the perception, we have no account of either. How will our philosopher get at *vision*, or make an eye? How should the blind animal affect sight, of which blind animals, we know, have neither conception nor desire? Affecting it, by what operation of its will, by what endeavour to see, could it so determine the fluids of its body, as to inchoate the formation of an eye? or, suppose the eye formed, would the perception follow? The same of the other senses. And this objection holds its force, ascribe what you will to the hand of time, to the power of habit, to changes too slow to be observed by man, or brought within any comparison which he is able to make of past things with the present: concede what you please to these arbitrary and unattested suppositions, how will they help you? Here is no inception. No laws, no course, no powers of nature which prevail at present, nor any analogous to these would give commencement to a new sense. And it is in vain to inquire,

how that might proceed which could never begin.

I think the senses to be the most inconsistent with the hypothesis before us, of any part of the animal frame. But other parts are sufficiently so. The solution does not apply to the parts of animals which have little in them of motion. If we could suppose joints and muscles to be gradually formed by action and exercise, what action or exercise could form a skull, or fill it with brains? No effort of the animal could determine the clothing of its skin. What *conatus* could give prickles to the porcupine or hedgehog, or to the sheep its fleece?

In the last place; What do these appetencies mean when applied to plants? I am not able to give a signification to the term, which can be transferred from animals to plants; or which is common to both. Yet a no less successful organization is found in plants, than what obtains in animals. A solution is wanted for one as well as the other.

Upon the whole; after all the schemes and struggles of a reluctant philosophy, the necessary resort is to a Deity. The marks of *design* are too strong to be gotten over. Design must have had a designer. That designer must have been a person. That person is GOD.

## CHAPTER XXIV.

## OF THE NATURAL ATTRIBUTES OF THE DEITY.

It is an immense conclusion, that there is a GOD; a perceiving, intelligent, designing, Being; at the head of creation, and from whose will it proceeded. The *attributes* of such a Being, suppose His reality to be proved, must be adequate to the magnitude, extent, and multiplicity of his operations: which are not only vast beyond comparison with those performed by any other power, but, so far as respects our conceptions of them, infinite, because they are unlimited on all sides.

Yet the contemplation of a nature so exalted, however surely we arrive at the proof of its existence, overwhelms our faculties. The mind feels its powers sink under the subject. One consequence of which is, that from painful abstraction the thoughts seek relief in sensible images. Whence may be deduced the ancient,

and almost universal propensity to idolatrous substitutions. They are the resources of a labouring imagination. False religions usually fall in with the natural propensity; true religions, or such as have derived themselves from the true, resist it.

It is one of the advantages of the revelations which we acknowledge, that, whilst they reject idolatry with its many pernicious accompaniments, they introduce the Deity to human apprehension, under an idea more personal, more determinate, more within its compass, than the theology of nature can do. And this they do by representing Him exclusively under the relation in which He stands to ourselves; and, for the most part, under some precise character, resulting from that relation, or from the history of His providences. Which method suits the span of our intellects much better than the universality which enters into the idea of God, as deduced from the views of nature. When, therefore, these representations are well founded in point of authority (for all depends upon that), they afford a condescension to the state of our faculties, of which they who have most reflected on the subject will be the first to acknowledge the want and the value.

Nevertheless, if we be careful to imitate the

documents of our religion, by confining our explanations to what concerns ourselves, and do not affect more precision in our ideas than the subject allows of, the several terms which are employed to denote the attributes of the Deity may be made, even in natural religion, to bear a sense consistent with truth and reason, and not surpassing our comprehension.

These terms are; Omnipotence, omniscience, omnipresence, eternity, self-existence, necessary existence, spirituality.

“Omnipotence,” “omniscience,” “infinite” power, “infinite” knowledge, are *superlatives*; expressing our conception of these attributes in the strongest and most elevated terms which language supplies. We ascribe power to the Deity under the name of “omnipotence,” the strict and correct conclusion being, that a power which could create such a world as this is, must be, beyond all comparison, greater than any which we experience in ourselves, than any which we observe in other visible agents; greater also than any which we can want, for our individual protection and preservation, in the Being upon whom we depend. It is a power, likewise, to which we are not authorized, by our observation or knowledge, to assign any limits of space or duration.

Very much of the same sort of remark is applicable to the term “omniscience,” infinite knowledge, or infinite wisdom. In strictness of language, there is a difference between knowledge and wisdom; wisdom always supposing action, and action directed by it. With respect to the first, viz. *knowledge*, the Creator must know, intimately, the constitution and properties of the things which He created; which seems also to imply a foreknowledge of their action upon one another, and of their changes; at least, so far as the same result from trains of physical and necessary causes. His omniscience also, as far as respects things present, is deducible from His nature, as an intelligent being, joined with the extent, or rather the universality, of His operations. Where He acts He is; and where He is, He perceives. The *wisdom* of the Deity, as testified in the works of creation, surpasses all idea we have of wisdom, drawn from the highest intellectual operations of the highest class of intelligent beings with whom we are acquainted; and, which is of the chief importance to us, whatever be its compass or extent, which it is evidently impossible that we should be able to determine, it must be adequate to the conduct of that order of things under which we live. And

this is enough. It is of very inferior consequence by what terms we express our notion, or rather our admiration, of this attribute. The terms, which the piety and the usage of language have rendered habitual to us, may be as proper as any other. We can trace this attribute much beyond what is necessary for any conclusion to which we have occasion to apply it. The degree of knowledge and power, requisite for the formation of created nature, cannot, with respect to us, be distinguished from infinite.

The Divine “omnipresence” stands, in natural theology, upon this foundation. In every part and place of the universe with which we are acquainted, we perceive the exertion of a power, which we believe, mediately or immediately, to proceed from the Deity. For instance; in what part or point of space, that has ever been explored, do we not discover attraction? In what regions do we not find light? In what accessible portion of our globe do we not meet with gravity, magnetism, electricity; together with the properties also and powers of organized substances, of vegetable or of animated nature? Nay further, we may ask, what kingdom is there of nature, what corner of space, in which there is anything that can be examined by us, where we do not fall upon

contrivance and design? The only reflection, perhaps, which arises in our minds from this view of the world around us is, that the laws of nature everywhere prevail; that they are uniform and universal. But what do we mean by the laws of nature, or by any law? Effects are produced by power, not by laws. A law cannot execute itself. A law refers us to an agent. Now an agency so general, as that we cannot discover its absence, or assign the place in which some effect of its continued energy is not found, may, in popular language at least, and, perhaps, without much deviation from philosophical strictness, be called universal: and, with not quite the same, but with no inconsiderable propriety, the person, or Being, in whom that power resides, or from whom it is derived, may be taken to be *omnipresent*. He who upholds all things by His power may be said to be everywhere present.

This is called a virtual presence. There is also what metaphysicians denominate an essential ubiquity; and which idea the language of Scripture seems to favour: but the former, I think, goes as far as natural theology carries us.

“Eternity” is a negative idea, clothed with a positive name. It supposes, in that to which it is applied, a present existence; and is the

negation of a beginning or an end of that existence. As applied to the Deity, it has not been controverted by those who acknowledge a Deity at all. Most assuredly there never was a time in which nothing existed, because that condition must have continued. The universal *blank* must have remained ; nothing could rise up out of it ; nothing could ever have existed since ; nothing could exist now. In strictness, however, we have no concern with duration prior to that of the visible world. Upon this article, therefore, of theology, it is sufficient to know that the contriver necessarily existed before the contrivance.

“Self-existence” is another negative idea, viz. the negation of a preceding cause, as of a progenitor, a maker, an author, a creator.

“Necessary existence” means demonstrable existence.

“Spirituality” expresses an idea, made up of a negative part and of a positive part. The negative part consists in the exclusion of some of the known properties of matter, especially of solidity, of the *vis inertiae*, and of gravitation. The positive part comprises perception, thought, will, power, *action*, by which last term is meant, the origination of motion ; the quality, perhaps, in which resides the essential superiority of spirit

over matter, "which cannot move, unless it be moved ; and cannot but move, when impelled by another."<sup>1</sup> I apprehend that there can be no difficulty in applying to the Deity both parts of this idea.

<sup>1</sup> Bishop Wilkin's Principles of Natural Religion, p. 106.

## CHAPTER XXV.

### THE UNITY OF THE DEITY.

OF the “Unity of the Deity,” the proof is, the *uniformity* of plan observable in the universe. The universe itself is a system; each part either depending upon other parts, or being connected with other parts by some common law of motion, or by the presence of some common substance. One principle of gravitation causes a stone to drop towards the earth, and the moon to wheel round it. One law of attraction carries all the different planets about the sun. This philosophers demonstrate. There are also other points of agreement amongst them, which may be considered as marks of the identity of their origin, and of their intelligent author. In all are found the conveniency and stability derived from gravitation. They all experience vicissitudes of days and nights, and changes of season. They all, at least Jupiter, Mars, and Venus,

---

have the same advantages from their atmosphere as we have. In all the planets the axes of rotation are permanent. Nothing is more probable than that the same attracting influence, acting according to the same rule, reaches to the fixed stars.

The undulations of light, too, which the sun produces are similar in character to those excited by the fixed stars. And it has been shown by the examination of this light of the fixed stars that they are bodies like our sun in constitution and in a high state of combustion. The heat of the sun, in kind, we know, too, differs nothing from the heat of a coal fire.

In our own globe the case is clearer. New countries are continually discovered, but the old laws of nature are always found in them : new plants perhaps, or animals, but always in company with plants and animals which we already know ; and always possessing many of the same general properties. We never get amongst such original, or totally different, modes of existence, as to indicate that we are come into the province of a different Creator, or under the direction of a different will. In truth, the same order of things attends us wherever we go. The elements act upon one another, electricity operates, the tides rise and fall, the

---

magnetic needle elects its position in one region of the earth and sea as well as in another. One atmosphere invests all parts of the globe, and connects all ; one sun illuminates ; one moon exerts its specific attraction upon all parts. If there be a variety in natural effects, as, e.g. in the tides of different seas, that very variety is the result of the same cause, acting under different circumstances. In many cases this is proved ; in all is probable.

The inspection and comparison of *living* forms add to this argument examples without number. Of all large terrestrial animals the structure is very much alike ; their senses nearly the same ; their natural functions and passions nearly the same ; their viscera nearly the same, both in substance, shape, and office : digestion, nutrition circulation, secretion go on, in a similar manner, in all ; the great circulating fluid is the same ; for, I think, but trifling difference has been discovered in the properties of *blood*, from whatever animal it be drawn. The *skeletons* also of the larger terrestrial animals show particular varieties, but still under a great general affinity. The resemblance is somewhat less, yet sufficiently evident, between quadrupeds and birds. They are all alike in five respects, for one in which they differ.

---

In *fish*, which belong to another department, as it were, of nature, the points of comparison become fewer. But we never lose sight of our analogy, e.g. we still meet with a stomach, a liver, a spine; with bile and blood; with teeth; with eyes (which eyes are only slightly varied from our own, and which variation, in truth, demonstrates not an interruption but a continuance of the same exquisite plan; for it is the adaptation of the organ to the element, viz. to the different refraction of light passing into the eye out of a denser medium). The provinces, also, themselves of water and earth, are connected by the species of animals which inhabit both; and also by a large tribe of aquatic animals, which closely resemble the terrestrial in their internal structure; I mean the cetaceous tribe, which have hot blood, respiring lungs, bowels, and other essential parts, like those of land animals. This similitude, surely, bespeaks the same creation and the same Creator.

*Insects* and *shell-fish* appear to me to differ from other classes of animals the most widely of any. Yet even here, beside many points of particular resemblance, there exists a general relation of a peculiar kind. It is the relation of inversion; the law of contrariety: namely, that, whereas, in other animals the bones to which

the muscles are attached lie *within* the body ; in insects and shell-fish they lie on the *outside* of it. The shell of a lobster performs to the animal the office of a *bony*, by furnishing to the tendons that fixed basis or immovable fulcrum, without which, mechanically, they could not act. The crust of an insect is its shell, and answers the like purpose. The shell also of an oyster stands in the place of a *bony* ; the bases of the muscles being fixed to it, in the same manner as, in other animals, they are fixed to the bones. All which (under wonderful varieties, indeed, and adaptations of form) confesses an imitation, a remembrance, a carrying on, of the same plan.

The observations here made are equally applicable to plants ; but, I think, unnecessary to be pursued. It is a very striking circumstance, and alone sufficient to prove all which we contend for, that, in this part likewise of organized nature, we perceive a continuation of the *sexual* system.

Certain however it is, that the whole argument for the divine unity goes no further than to a unity of counsel.

It may likewise be acknowledged, that no arguments which we are in possession of exclude the ministry of subordinate agents. If

such there be, they act under a presiding, a controlling will ; because they act according to certain general restrictions, by certain common rules, and, as it should seem, upon a general plan : but still such agents, and different ranks, and classes, and degrees of them, may be employed.

## CHAPTER XXVI.

## THE GOODNESS OF THE DEITY.

The proof of the *divine goodness* rests upon two propositions : each, as we contend, capable of being made out by observations drawn from the appearances of nature.

“The first is that, in a vast plurality of instances in which contrivance is perceived the design of the contrivance is *beneficial*. ”

The second, “that the Deity has superadded *pleasure* to animal sensations, beyond what was necessary for any other purpose, or when the purpose, so far as it was necessary, might have been effected by the operation of pain.”

First, “in a vast plurality of instances in which contrivance is perceived, the design of the contrivance is *beneficial*. ”

No production of nature displays contrivance so manifestly as the parts of animals ; and the parts of animals have all of them, I believe, a

---

real, and with very few exceptions, all of them a known and intelligible subserviency to the use of the animal. Now, when the multitude of animals is considered, the number of parts in each, their figure and fitness, the faculties depending upon them, the variety of species, the complexity of structure, the success, in so many cases, and felicity of the result, we can never reflect, without the profoundest adoration, upon the character of that Being from whom all these things have proceeded: we cannot help acknowledging what an exertion of benevolence creation was; of a benevolence how minute in its care, how vast in its comprehension!

When we appeal to the parts and faculties of animals, and to the limbs and senses of animals in particular, we state, I conceive, the proper medium of proof for the conclusion which we wish to establish. I will not say that the insensible parts of nature are made solely for the sensitive parts: but this I say, that, when we consider the benevolence of the Deity, we can only consider it in relation to sensitive being. Without this reference or referred to anything else, the attribute has no object; the term has no meaning. Dead matter is nothing. The parts, therefore, especially the limbs and senses

of animals, although they constitute, in mass and quantity, a small portion of the material creation, yet, since they alone are instruments of perception, they compose what may be called the whole of visible nature, estimated with a view to the disposition of its Author. Consequently, it is in *these* that we are to seek his character. It is by these that we are to prove that the world was made with a benevolent design.

Nor is the design abortive. It is a happy world after all. The air, the earth, the water, teem with delighted existence. In a spring noon, or a summer evening, on whichever side I turn my eyes, myriads of happy beings crowd upon my view. “The insect youth are on the wing.” Swarms of new-born *flies* are trying their pinions in the air. Their sportive motions, their wanton mazes, their gratuitous activity, their continual change of place without use or purpose, testify their joy, and the exultation which they feel in their lately discovered faculties. A *bee* amongst the flowers in spring is one of the most cheerful objects that can be looked upon. Its life appears to be all enjoyment; so busy, and so pleased: yet it is only a specimen of insect life, with which, by reason of the animal being half domesticated, we happen

to be better acquainted than we are with that of others. The *whole winged* insect tribe, it is probable, are equally intent upon their proper employments, and, under every variety of constitution, gratified, and perhaps equally gratified, by the offices which the Author of their nature has assigned to them. But the atmosphere is not the only scene of enjoyment for the insect race. Plants are covered with aphides, greedily sucking their juices, and constantly, as it should seem, in the act of sucking. It cannot be doubted but that this is a state of gratification. What else should fix them so close to the operation, and so long? other species are *running about*, with an alacrity in their motions, which carries with it every mark of pleasure. Large patches of ground are sometimes half covered with these brisk and sprightly natures. If we look to what the *waters* produce, shoals of the fry of fish frequent the margins of rivers, of lakes, and of the sea itself. These are so happy, that they know not what to do with themselves. Their attitudes, their vivacity, their leaps out of the water, their frolics in it (which I have noticed a thousand times with equal attention and amusement), all conduce to show their excess of spirits, and are simply the effects of that excess. Walking by the sea-side, in a

calm evening, upon a sandy shore, and with an ebbing tide, I have frequently remarked the appearance of a dark cloud, or rather, very thick mist, hanging over the edge of the water, to the height, perhaps, of half a yard, and of the breadth of two or three yards, stretching along the coast as far as the eye could reach, and always retiring with the water. When this cloud came to be examined, it proved to be nothing else than so much space, filled with young *shrimps*, in the act of bounding into the air from the shallow margin of the water, or from the wet sand. If any motion of a mute animal could express delight, it was this: if they had meant to make signs of their happiness, they could not have done it more intelligibly. Suppose then, what I have no doubt of, each individual of this number to be in a state of positive enjoyment; what a sum, collectively, of gratification and pleasure have we here before our view!

The *young* of all animals appear to me to receive pleasure simply from the exercise of their limbs and bodily faculties, without reference to any end to be attained, or any use to be answered by the exertion. A child, without knowing any thing of the use of language, is in a high degree delighted with being able to speak. Its incessant repetition of a few articulate sounds, or perhaps

---

of the single word which it has learned to pronounce, proves this point clearly. Nor is it less pleased with its first successful endeavours to walk, or rather to run (which precedes walking), although entirely ignorant of the importance of the attainment to its future life, and even without applying it to any present purpose. A child is delighted with speaking, without having anything to say; and with walking, without knowing where to go. And, prior to both these, I am disposed to believe that the waking hours of infancy are agreeably taken up with the exercise of vision, or perhaps, more properly speaking, with learning to see.

But it is not for youth alone that the great Parent of creation hath provided. Happiness is found with the purring cat, no less than with the playful kitten; in the arm-chair of dozing age, as well as in either the sprightliness of the dance, or the animation of the chase. To novelty, to acuteness of sensation, to hope, to ardour of pursuit, succeeds what is, in no inconsiderable degree, an equivalent for them all, “perception of ease.” Herein is the exact difference between the young and the old. The young are not happy but when enjoying pleasure; the old are happy when free from pain. And this constitution suits with the degrees of

animal power which they respectively possess. The vigour of youth was to be stimulated to action by impatience of rest; whilst to the imbecility of age quietness and repose become positive gratifications. In one important respect the advantage is with the old. A state of ease is, generally speaking, more attainable than a state of pleasure. A constitution, therefore, which can enjoy ease is preferable to that which can taste only pleasure. This same perception of ease oftentimes renders old age a condition of great comfort; especially when riding at its anchor after a busy or tempestuous life. It is well described by Rousseau to be the interval of repose and enjoyment between the hurry and the end of life. How far the same cause extends to other animal natures cannot be judged of with certainty. The appearance of satisfaction with which most animals, as their activity subsides, seek and enjoy rest, affords reason to believe that this source of gratification is appointed to advanced life under all, or most of its various forms. In the species with which we are best acquainted, namely our own, I am far, even as an observer of human life, from thinking that youth is its happiest season, much less the only happy one; as a Christian, I am willing to believe that there is a great deal of truth in the

---

following representation, given by a very pious writer, as well as excellent man.<sup>1</sup> “To the intelligent and virtuous old age presents a scene of tranquil enjoyments, of obedient appetite, of well-regulated affection, of maturity in knowledge, and of calm preparation for immortality. In this serene and dignified state, placed as it were on the confines of two worlds, the mind of a good man reviews what is past with the complacency of an approving conscience ; and looks forward with humble confidence in the mercy of God, and with devout aspirations towards His eternal and ever-increasing favour.”

What is seen in different stages of the same life, is still more exemplified in the lives of different animals. Animal enjoyments are infinitely *diversified*. The modes of life, to which the organization of different animals respectively determines them, are not only of various but of opposite kinds. Yet each is happy in its own. For instance, animals of prey live much alone ; animals of a milder constitution, in society. Yet the herring, which lives in shoals, and the sheep, which lives in flocks, are not more happy in a crowd, or more contented amongst their companions, than is

<sup>1</sup> Father’s Instructions ; by Dr. Percival of Manchester, p. 317.

the pike, or the lion, with the deep solitudes of the pool or the forest.

But it will be said that the instances which we have here brought forward, whether of vivacity or repose, or of apparent enjoyment derived from either, are picked and favourable instances. We answer, first, that they are instances, nevertheless, which comprise large provinces of sensitive existence; that every case which we have described is the case of millions. At this moment, in every given moment of time, how many myriads of animals are eating their food, gratifying their appetites, ruminating in their holes, accomplishing their wishes, pursuing their pleasures, taking their pastimes! In each individual how many things must go right for it to be at ease; yet how large a proportion out of every species is so in every assignable instant! Secondly, we contend, in the terms of our original proposition, that throughout the whole of life, as it is diffused in nature, and as far as we are acquainted with it, looking to the average of sensations, the plurality and the preponderancy is in favour of happiness by a vast excess. In our own species, in which perhaps the assertion may be more questionable than in any other, the preponderance of good over evil, of

health, for example, and ease, over pain and distress, is evinced by the very notice which calamities excite. What inquiries does the sickness of our friends produce! What conversation their misfortunes! This shows that the common course of things is in favour of happiness; that happiness is the rule, misery the exception. Were the order reversed, our attention would be called to examples of health and competency, instead of disease and want. And how much, it may be added, of what we do suffer, both bodily and mentally, is due to a reckless abuse of the blessings bestowed upon us.

One great cause of our insensibility to the goodness of the Creator, is the very *extensiveness* of His bounty. We prize but little what we share in common with the rest, or with the generality of our species. When we hear of blessings, we think forthwith of successes, of prosperous fortunes, of honours, riches, preferments, i.e. of those advantages and superiorities over others, which we happen either to possess, or to be in pursuit of, or to covet. The common benefits of our nature entirely escape us. Yet these are the great things. These constitute what most properly ought to be accounted blessings of Providence; what alone, if we

might so speak, are worthy of its care. Nightly rest and daily bread, the ordinary use of our limbs, and senses, and understandings, are gifts which admit of no comparison with any other. Yet, because almost every man we meet with possesses these, we leave them out of our enumeration. They raise no sentiment; they move no gratitude. Now, herein is our judgment perverted by our selfishness. A blessing ought in truth to be the *more* satisfactory, the bounty at least of the donor is rendered more conspicuous, by its very diffusion, its commonness, its cheapness; by its falling to the lot, and forming the happiness, of the great bulk and body of our species, as well as of ourselves. Nay, even when we do not possess it, it ought to be matter of thankfulness that others do. But we have a different way of thinking. We court distinction. That is not the worst: we *see* nothing but what has distinction to recommend it. This necessarily contracts our views of the Creator's beneficence within a narrow compass; and most unjustly. It is in those things which are so common as to be no distinction, that the amplitude of the Divine benignity is perceived.

But pain, no doubt, and privations exist, in numerous instances, and to a degree which, collectively, would be very great, if they were

---

compared with any other thing than with the mass of animal fruition. For the application, therefore, of our proposition to that *mixed* state of things which these exceptions induce, two rules are necessary, and both, I think, just and fair rules. One is, that we regard those effects alone which are accompanied with proofs of intention: the other, that when we cannot resolve all appearances into benevolence of design, we make the few give place to many; the little to the great; that we take our judgment from a large and decided preponderancy, if there be one.

I crave leave to transcribe into this place, what I have said upon this subject in my Moral Philosophy :—

“ When God created the human species, either He wished their happiness, or He wished their misery, or He was indifferent and unconcerned about either.

“ If He had wished their misery, He might have made sure of His purpose, by forming our senses to be so many sores and pains to us, as they are now instruments of gratification and enjoyment: or by placing us amidst objects, so ill suited to our perceptions as to have continually offended us, instead of ministering to our refreshment and delight. He might have

made, for example, everything we tasted bitter; everything we saw, loathsome; everything we touched, a sting; every smell, a stench; and every sound, a discord.

“If He had been indifferent about our happiness or misery, we must impute to our good fortune (as all design by this supposition is excluded) both the capacity of our senses to receive pleasure, and the supply of external objects fitted to produce it.

“But either of these, and still more both of them, being too much to be attributed to accident, nothing remains but the first supposition, that God, when He created the human species, wished their happiness; and made for them the provision which He has made, with that view and for that purpose.

“The same argument may be proposed in different terms; *thus*: contrivance proves design: and the predominant tendency of the contrivance indicates the disposition of the designer. The world abounds with contrivances: and all the contrivances which we are acquainted with are directed to beneficial purposes. Evil, no doubt, exists; but is never, that we can perceive, the object of contrivance. Teeth are contrived to eat, not to ache; their aching now and then is incidental to the contrivance, perhaps inseparable

---

from it: or even, if you will, let it be called a defect in the contrivance; but it is not the object of it. This is a distinction which well deserves to be attended to. In describing implements of husbandry, you would hardly say of the sickle, that it is made to cut the reaper's hand; though, from the construction of the instrument, and the manner of using it, this mischief often follows. But if you had occasion to describe instruments of torture or execution; this engine, you would say, is to extend the sinews; this to dislocate the joints; this to break the bones; this to scorch the soles of the feet. Here pain and misery are the very object of the contrivance. Now, nothing of this sort is to be found in the works of nature. We never discover a train of contrivance to bring about an evil purpose. No anatomist ever discovered a system of organization calculated to produce pain and disease; or, in explaining the parts of the human body, ever said, this is to irritate; this to inflame; this duct is to convey the gravel to the kidneys; this gland to secrete the humour which forms the gout: if by chance he come at a part of which he knows not the use, the most he can say is, that it is useless; no one ever suspects that it is put there to incommodate, to annoy, or to torment."

The TWO CASES which appear to me to have the most of difficulty in them, as forming the most of the appearance of exception to the representation here given, are those of *venomous* animals, and of animals *preying* upon one another. These properties of animals, wherever they are found, must, I think, be referred to design; because there is, in all cases of the first, and in most cases of the second, an express and distinct organization provided for the producing of them. Under the first head, the fangs of vipers, the stings of wasps and scorpions, are as clearly intended for their purpose, as any animal structure is for any purpose the most incontestibly beneficial. And the same thing must, under the second head, be acknowledged of the talons and beaks of birds, of the tusks, teeth and claws of beasts of prey, of the shark's mouth, of the spider's web, and of numberless weapons of offence belonging to different tribes of voracious insects. We cannot, therefore, avoid the difficulty by saying, that the effect was not intended. The only question open to us is, whether it be ultimately evil. From the confessed and felt imperfection of our knowledge, we ought to presume, that there may be consequences of this economy which are hidden from us; from the benevolence which pervades

---

the general designs of nature, we ought also to presume that these consequences, if they could enter into our calculation, would turn the balance on the favourable side. Both these I contend to be reasonable presumptions. Not reasonable presumptions, if these two cases were the only cases which nature presented to our observation ; but reasonable presumptions under the reflection, that the cases in question are combined with a multitude of intentions, all proceeding from the same Author, and all, except these, directed to ends of undisputed utility. Of the vindications, however, of this economy, which we are able to assign, such as most extenuate the difficulty are the following.

With respect to *venomous* bites and stings, it may be observed,—

That, the animal itself being regarded, the faculty complained of is *good*: being conducive, in all cases, to the defence of the animal; in some cases, to the subduing of its prey; and in some, probably to the killing of it when caught, by a mortal wound inflicted in the passage to the stomach, which may be no less merciful to the victim than salutary to the devourer: for death is certain, rapid and comparatively painless. Indeed there seems to be no reason for taking the venomous serpents out of the suc-

ceeding category; as their peculiar means of destroying their prey can only be regarded as a variety in the construction and adaptation of the ordinary weapons of destruction.

It has been, I think, very justly remarked, concerning serpents, that, whilst only a few species possess the venomous property, that property guards the whole tribe. The most innocuous snake is avoided with as much care as a viper. Now the terror with which large animals regard this class of reptiles is its protection; and this terror is founded in the formidable revenge, which a few of the number, compared with the whole, are capable of taking.

The SECOND CASE, viz. that of animals *devouring* one another, furnishes a consideration of much larger extent. To judge whether, as a general provision, this can be deemed an *evil*, even so far as we understand its consequences, which, probably, is a partial understanding, the following reflections are fit to be attended to.

1. Immortality upon this earth is out of the question. Without death there could be no generation, no sexes, no parental relation, i. e. as things are constituted, no animal happiness. The particular duration of life, assigned to different animals, can form no part of the objection; because, whatever that duration be,

whilst it remains finite and limited, it may always be asked, why it is no longer. The natural age of different animals varies from a single day to a century of years. No account can be given of this; nor could any be given, whatever other proportion of life had obtained amongst them.

The term then of life in different animals being the same as it is, the question is, what mode of taking it away is the best even for the animal itself?

Now, according to the established order of nature (which we must suppose to prevail, or we cannot reason at all upon the subject), the three methods by which life is usually put an end to are, acute diseases, decay, and violence. The simple and natural life of *brutes* is not often visited by acute distempers; nor could it be deemed an improvement of their lot if they were. Let it be considered, therefore, in what a condition of suffering and misery a brute animal is placed, which is left to perish by *decay*. In human sickness or infirmity, there is the assistance of man's rational fellow-creatures, if not to alleviate his pains, at least to minister to his necessities, and to supply the place of his own activity. A brute, in his wild and natural state, does everything for himself. When his

strength, therefore, or his speed, or his limbs, or his teeth, or his senses fail him, he is delivered over, either to absolute famine, or to the protracted wretchedness of a life slowly wasted by the scarcity of food. Is it then to see the world filled with drooping, superannuated, half-starved, helpless and unhelped animals, that you would alter the present system of pursuit and prey ?

2. Which system is also to them the spring of motion and activity on both sides. The pursuit of its prey, forms the employment, and appears to constitute the pleasure, of a considerable part of the animal creation. The using of the means of defence, or flight, or precaution, forms also the business of another part. And even of this latter tribe, we have no reason to suppose that their happiness is much molested by their fears. Their danger exists continually ; and in some cases they seem to be so far sensible of it, as to provide in the best manner they can against it ; but it is only when the attack is actually made upon them that they appear to suffer from it. To contemplate the insecurity of their condition with anxiety and dread, requires a degree of reflection which (happily for themselves) they do not possess. A *hare*, notwithstanding the number of its

dangers and its enemies, is as playful an animal as any other. It cannot, therefore, be doubted, as already suggested, that by the rapid destruction of the maimed, the diseased, and the aged, the sum of the happiness and enjoyment of animal life is greatly enhanced; whilst sustenance is provided for the young and healthy.

3. But, to do justice to the question, the system of animal *destruction* ought always to be considered in strict connexion with another property of animal nature, viz. *superfecundity*. They are countervailing qualities. One subsists by the correction of the other. In treating, therefore, of the subject under this view (which is, I believe, the true one), our business will be, first, to point out the advantages which are gained by the powers in nature of a superabundant multiplication; and then to show, that these advantages are so many reasons for appointing that system of natural hostilities, which we are endeavouring to account for.

In almost all cases nature produces her supplies with profusion. A single cod-fish spawns, in one season, a greater number of eggs than all the inhabitants of England amount to. A thousand other instances of prolific generation might be stated, which, though not equal to this, would carry on the increase of

the species with a rapidity which outruns calculation, and to an immeasurable extent. The advantages of such a constitution are two : first, that it tends to keep the world always full ; whilst, secondly, it allows the proportion between the several species of animals to be differently modified, as different purposes require, or as different situations may afford for them room and food. Where this vast fecundity meets with a vacancy fitted to receive the species, there it operates with its whole effect : there it pours in its numbers, and replenishes the waste. We complain of what we call the exorbitant multiplication of some troublesome insects ; not reflecting, that large portions of nature might be left void without it. If the accounts of travellers may be depended upon, immense tracts of forest in North America would be nearly lost to sensitive existence, if it were not for *gnats*. “In the thinly inhabited regions of America, in which the waters stagnate and the climate is warm, the whole air is filled with crowds of these insects.” Thus it is that, where we looked for solitude and death-like silence, we meet with animation, activity, enjoyment ; with a busy, a happy, and a peopled world. Again, hosts of *mice* are reckoned amongst the plagues of the north-east part of Europe ; whereas vast

plains in Siberia, as we learn from good authority, would be lifeless without them. The Caspian deserts are converted by their presence into crowded warrens. Between the Volga and the Yaik, and in the country of Hyrcania, the ground, says Pallas, is in many places *covered* with little hills, raised by the earth cast out in forming the burrows. Do we so envy these blissful abodes, to pronounce the fecundity by which they are supplied with inhabitants to be an evil; a subject of complaint, and not of praise? Further; by virtue of this same superfecundity, what we term destruction becomes almost instantly the parent of life. What we call blights are oftentimes legions of animated beings, claiming their portion in the bounty of nature. What corrupts the produce of the earth to us, prepares it for them. And it is by means of their rapid multiplication that they take possession of their pasture: a slow propagation would not meet the opportunity.

But in conjunction with the occasional use of this fruitfulness, we observe also, that it allows the proportion between the several species of animals to be differently modified, as different purposes of utility may require. When the forests of America come to be cleared, and the swamps drained, our gnats will give place to

other inhabitants. As the population of Europe spreads to the north and the east, the mice retire before the husbandman and the shepherd, and yield their station to herds and flocks. In what concerns the human species, it may be a part of the scheme of Providence, that the earth should be inhabited by a shifting, or perhaps a circulating population. In this economy it is possible that there may be the following advantages: when old countries are become exceedingly corrupt, simpler modes of life, purer morals, and better institutions, may rise up in new ones, whilst fresh soils reward the cultivator with more plentiful returns. Thus the different portions of the globe come into use in succession as the residence of man; and in his absence entertain other guests, which, by their sudden multiplication, fill the chasm. In domesticated animals, we find the effect of their fecundity to be, that we can always command numbers; we can always have as many of any particular species as we please, or as we can support.<sup>4</sup> Nor do we complain of its excess; it being much more easy to regulate abundance, than to supply scarcity.

But then this *superfecundity*, though of great occasional use and importance, exceeds the ordinary capacity of nature to receive or support its

progeny. All superabundance supposes destruction, or must destroy itself. Perhaps there is no species of terrestrial animals whatever, which would not overrun the earth, if it were permitted to multiply in perfect safety ; or of fish, which would not fill the ocean : at least, if any single species were left to their natural increase without disturbance or restraint, the food of other species would be exhausted by their maintenance. It is necessary, therefore, that the effects of such prolific faculties be curtailed. In conjunction with other checks and limits, all subservient to the same purpose, are the *thinnings* which take place among animals, by their action upon one another. In some instances we ourselves experience, very directly, the use of these hostilities. One species of insects rids us of another species ; or reduces their ranks. A third species, perhaps, keeps the second within bounds ; and birds or lizards are a fence against the inordinate increase by which even these last might infest us. In other more numerous, and possibly more important instances, this disposition of things, although less necessary or useful to us, and of course less observed by us, may be necessary and useful to certain other species ; or even for the preventing of the loss of certain species from the universe : a misfortune which

seems to be studiously guarded against. Though there may be the appearance of failure in some of the details of Nature's works, in her great purposes there never are. Her species never fail. The provision, which was originally made for continuing the replenishment of the world, has proved itself to be effectual through a long succession of ages.

What further shows that the system of destruction amongst animals holds an express relation to the system of fecundity ; that they are parts indeed of one compensatory scheme ; is that in each species the fecundity bears a proportion to the smallness of the animal, to its weakness, to the shortness of its natural term of life, and to the dangers and enemies by which it is surrounded. An elephant produces but one calf ; a butterfly lays six hundred eggs. Birds of prey seldom produce more than two eggs : the sparrow tribe, and the duck tribe, frequently sit upon a dozen. In the rivers, we meet with a thousand minnows for one pike ; in the sea, a million of herrings for a single shark. Compensation obtains throughout. Defencelessness and devastation are repaired by fecundity.

We have dwelt the longer on these considerations, because the subject to which they apply namely, that of animals *devouring* one another,

forms the chief, if not the only instance, in the works of the Deity, of an economy, stamped by marks of design, in which the character of utility can, with any semblance of plausibility, be called in question. The case of *venomous* animals is of much inferior consequence to the case of prey, and may in fact be included under it.

OUR FIRST PROPOSITION, and that which we have hitherto been defending, was, "that in a vast plurality of instances in which *contrivance* is perceived, the design of the contrivance is beneficial."

OUR SECOND PROPOSITION is, "that the Deity has added *pleasure* to animal sensations, beyond what was necessary for any other purpose, or when the purpose, so far as it was necessary, might have been effected by the operation of pain."

This proposition may be thus explained : the capacities which, according to the established course of nature, are *necessary* to the support or preservation of an animal, however manifestly they may be the result of an organization contrived for the purpose, can only be deemed an act or a part of the same will, as that which decreed the existence of the animal itself ; because, whether the creation proceeded from a benevo-

lent or a malevolent being, these capacities must have been given, if the animal existed at all. Animal properties, therefore, which fall under this description do not strictly prove the goodness of God : they may prove the existence of the Deity ; they may prove a high degree of power and intelligence : but they do not prove His goodness ; forasmuch as they must have been found in any creation which was capable of continuance, although it is possible to suppose that such a creation might have been produced by a being whose views rested upon misery.

But there is a class of properties, which may be said to be superadded from an intention expressly directed to happiness ; an intention to give a happy existence distinct from the general intention of providing the means of existence ; and that is, of capacities for pleasure, in cases wherein, so far as the conservation of the individual or of the species is concerned, they were not wanted, or wherein the purpose might have been secured by the operation of pain. The provision which is made of a variety of objects, not necessary to life, and ministering only to our pleasures ; and the properties given to the necessities of life themselves, by which they contribute to pleasure as well as preservation ;

show a further design, than that of giving existence.<sup>1</sup>

A single instance will make all this clear. Assuming the necessity of food for the support of animal life ; it is requisite that the animal be provided with organs, fitted for the procuring, receiving and digesting of its food. It may be also necessary that the animal be impelled by its sensations to exert its organs. But the pain of hunger would do all this. Why add pleasure to the act of eating ; sweetness and relish to food ? why a new and appropriate sense for the perception of the pleasure ? Why should the juice of a peach, applied to the palate, affect the part so differently from what it does when rubbed upon the palm of the hand ? This is a constitution which, so far as appears to me, can be resolved into nothing but the pure benevolence of the Creator. Eating is necessary ; but the pleasure attending it is not necessary : and that this pleasure depends, not only upon our being in possession of the sense of taste, which is different from every other, but upon a particular state of

<sup>1</sup> See this topic considered in Dr. Balguy's Treatise upon the Divine Benevolence. This excellent author first, I think, proposed it ; and nearly in the terms in which it is here stated. Some other observations also under this head are taken from that treatise.

the organ in which it resides, a felicitous adaptation of the organ to the object, will be confessed by any one who may happen to have experienced that vitiation of taste which frequently occurs in fevers, when every taste is irregular, and every one bad.

In mentioning the gratifications of the palate, it may be said that we have made choice of a trifling example. I am not of that opinion. They afford a share of enjoyment to man; but to brutes I believe that they are of very great importance. A horse at liberty passes a great part of his waking hours in eating. To the ox, the sheep, the deer, and other ruminating animals, the pleasure is doubled. Their whole time almost is divided between browsing upon their pasture and chewing their cud. Whatever the pleasure be, it is spread over a large portion of their existence. As there are animals which swallow their prey whole, and at once, without any time, as it should seem, for either drawing out or relishing the taste in the mouth, is it an improbable conjecture that a sense of pleasure, whether it be taste or not, accompanies the dissolution of the food in that receptacle, which dissolution in general is carried on very slowly? If this opinion be right, they are more than repaid for the defect of palate. The feasts last as long

as the digestion. Moreover, the sense of taste is adapted to the habits of the animal, flesh being as nauseous to the vegetable feeder as herbs are to the carnivora. In man the range of the senses of both taste and smell is more varied, and the enjoyment derived therefrom correspondingly greater.

In seeking for argument, we need not stay to insist upon the comparative importance of our example ; for the observation holds equally of all, or of three at least, of the other senses. The necessary purposes of hearing might have been answered without harmony ; of smell, without fragrance ; of vision, without beauty. Now, “if the Deity had been indifferent about our happiness or misery, we must impute to our good fortune (as all design by this supposition is excluded), both the capacity of our senses to receive pleasure, and the supply of external objects fitted to excite it.” I allege these as *two* felicities, for they are different things, yet both necessary : the sense being formed, the objects which were applied to it might not have suited it ; the objects being fixed, the sense might not have agreed with them. A coincidence is here required, which no accident can account for. There are three possible suppositions upon the subject, and no more. The

first ; that the sense, by its original constitution, was made to suit the object : the second ; that the object, by its original constitution, was made to suit the sense : the third ; that the sense is so constituted, as to be able, either universally, or within certain limits, by habit and familiarity, to render every object pleasant. Whichever of these suppositions we adopt, the effect evinces, on the part of the Author of Nature, a studious benevolence. If the pleasures which we derive from any of our senses depend upon an original congruity between the sense and the properties perceived by it, we know by experience that the adjustment demanded, with respect to the qualities which were conferred upon the objects that surround us, not only choice and selection, out of a boundless variety of possible qualities with which these objects might have been endued, but a *proportioning also of degree*, because an excess or defect of intensity spoils the perception, as much almost as an error in the kind and nature of the quality. Likewise the degree of dulness or acuteness in the sense itself is no arbitrary thing, but, in order to preserve the congruity here spoken of, requires to be in an exact or near correspondence with the strength of the impression. The dulness of the senses

---

forms the complaint of old age. Persons in fevers, and some other diseases, experience great torment from their preternatural acuteness. An increased, no less than an impaired sensibility, induces a state of disease and suffering.

The doctrine of a specific congruity, between animal senses and their objects, is strongly favoured by what is observed of insects in the election of their food. Some of these will feed upon one kind of plant or animal, and upon no other : some caterpillars upon the cabbage alone ; some upon the black currant alone : the silk-worm selects the mulberry. The species of caterpillar which eats the vine will starve upon the elder : nor will that which we find upon fennel, touch the rose-bush. Some insects confine themselves to two or three kinds of plants or animals. Some again show so strong a preference as to afford reason to believe that, though they may be driven by hunger to others, they are led by the pleasure of taste to a few particular plants alone : and all this, as it should seem, independently of habit or imitation.

But should we accept the third hypothesis, and even carry it so far, as to ascribe everything which concerns the question to habit (as in certain species, the human species most particularly, there is reason to attribute something),

we have then before us an animal capacity, not less perhaps to be admired than the native congruities which the other scheme adopts. It cannot be shown to result from any fixed necessity in nature, that what is frequently applied to the senses should of course become agreeable to them. It is, so far as it subsists, a power of accommodation provided in these senses by the Author of their structure, and forms a part of their perfection.

In whichever way we regard the senses, they appear to be specific gifts, ministering not only to preservation but to pleasure. But what we usually call the *senses* are probably themselves far from being the only vehicles of enjoyment, or the whole of our constitution which is calculated for the same purpose. We have many internal sensations of the most agreeable kind, hardly referable to any of the five senses. These would appear to be due to the healthy balance of all the functions which minister and are essential to life : and the complacency which we thus experience constitutes the difference between a passive existence and an active enjoyment of life. All this is true, and what reason can be assigned for it, except the will of the Creator ? It may reasonably be asked, why is anything a pleasure ? and I know no answer

which can be returned to the question, but that which refers it to appointment.

We can give no account whatever of our pleasures in the simple and original perception ; and, even when physical sensations are assumed, we can seldom account for them in the secondary and complicated shapes, in which they take the name of diversions. I never yet met with a sportsman, who could tell me in what the sport consisted ; who could resolve it into its principle, and state that principle. I have been a great follower of fishing myself, and in its cheerful solitude have passed some of the happiest hours of a sufficiently happy life ; but, to this moment, I could never trace out the source of the pleasure which it afforded me.

The “quantum in rebus inane !” whether applied to our amusements, or to our graver pursuits (to which in truth it sometimes equally belongs), is always an unjust complaint. If trifles engage, and if trifles makes us happy, the true reflection suggested by the experiment is upon the tendency of nature to gratification and enjoyment ; which is, in other words, the goodness of its Author towards His sensitive creation.

Rational natures also, as such, exhibit qualities which help to confirm the truth of our

position. The degree of understanding found in mankind is usually much greater than what is necessary for mere preservation. The pleasure of choosing for themselves, and of prosecuting the object of their choice, should seem to be an original source of enjoyment. The pleasures received from things great, beautiful, or new, from imitation, or from the liberal arts, are in some measure not only superadded but unmixed gratifications, having no pains to balance them.<sup>1</sup>

I do not know whether our attachment to *property* be not something more than the mere dictate of reason, or even than the mere effect of association. Property communicates a charm to whatever is the object of it. It is the first of our abstract ideas; it cleaves to us the closest and the longest. It endears to the child its plaything, to the peasant his cottage, to the landholder his estate. It supplies the place of prospect and scenery. Instead of coveting the beauty of distant situations, it teaches every man to find it in his own. It gives boldness and grandeur to plains and fens, tinge and colouring to clays and fallows.

All these considerations come in aid of our

<sup>1</sup> Balguy on the Divine Benevolence.

*second* proposition. The reader will now bear in mind what our two propositions were. They were, firstly, that in a vast plurality of instances in which contrivance is perceived, the design of the contrivance is beneficial: secondly, that the Deity has added pleasure to animal sensations beyond what was necessary for any other purpose; or when the purpose, so far as it was necessary, might have been effected by the operation of pain.

Whilst these propositions can be maintained, we are authorized to ascribe to the Deity the character of benevolence: and what is benevolence at all, must in Him be *infinite* benevolence, by reason of the infinite, that is to say, the incalculably great number of objects upon which it is exercised.

Of the ORIGIN OF EVIL no universal solution has been discovered; I mean, no solution which reaches to all cases of complaint. The most comprehensive is that which arises from the consideration of *general rules*. We may, I think without much difficulty, be brought to admit the four following points: first, that important advantages may accrue to the universe from the order of nature proceeding according to general laws: secondly, that general laws, how-

ever well set and constituted, often thwart and cross one another: thirdly, that from these thwartings and crossings, frequent particular inconveniences will arise: and, fourthly, that it agrees with our observation to suppose, that some degree of these inconveniences takes place in the works of nature. These points may be allowed; and it may also be asserted, that the general laws with which we are acquainted are directed to beneficial ends. On the other hand, with many of these laws we are not acquainted at all, or we are totally unable to trace them in their branches, and in their operation; the effect of which ignorance is, that they cannot be of importance to us as measures by which to regulate our conduct. The conservation of them may be of importance in other respects, or to other beings, but we are uninformed of their value or use; uninformed, consequently, when, and how far, they may or may not be suspended, or their effects turned aside, by a presiding and benevolent will, without incurring greater evils than those which would be avoided. The consideration therefore of general laws, although it may concern the question of the origin of evil very nearly (which I think it does), rests in views disproportionate to our faculties, and in a knowledge which we do not

possess. It serves rather to account for the obscurity of the subject, than to supply us with distinct answers to our difficulties. However, whilst we assent to the above stated propositions as principles, whatever uncertainty we may find in the application, we lay a ground for believing that cases of apparent evil, for which we can suggest no particular reason, are governed by reasons which are more general, which lie deeper in the order of second causes, and which on that account are removed to a greater distance from us.

The doctrine of *imperfections*, or, as it is called, of evils of imperfection, furnishes an account, founded, like the former, in views of universal nature. The doctrine is briefly this:—It is probable that creation may be better replenished by sensitive beings of different sorts, than by sensitive beings all of one sort. It is likewise probable that it may be better replenished by different orders of beings rising one above another in gradation, than by beings possessed of equal degrees of perfection. Now, a gradation of such beings implies a gradation of imperfections. No class can justly complain of the imperfections which belong to its place in the scale, unless it were allowable for it to complain, that a scale of being was appointed in

nature; for which appointment there appear to be reasons of wisdom and goodness.

In like manner *finiteness*, or what is resolvable into finiteness, in inanimate subjects, can never be a just subject of complaint, because if it were ever so, it would be always so: we mean, that we can never reasonably demand that things should be larger or more, when the same demand might be made, whatever the quantity or number was.

And to me it seems that the sense of mankind has so far acquiesced in these reasons, as that we seldom complain of evils of this class, when we clearly perceive them to be such. What I have to add, therefore, is that we ought not to complain of some other evils which stand upon the same foot of vindication as evils of confessed imperfection. We never complain that the globe of our earth is too small: nor should we complain, if it were even much smaller. But where is the difference to us between a less globe, and part of the present being uninhabitable? The inhabitants of an island may be apt enough to murmur at the sterility of some parts of it, against its rocks, or sands, or swamps; but no one thinks himself authorized to murmur, simply because the island is not larger than it is. Yet these are the same griefs.

The above are the two metaphysical answers which have been given to this great question. They are not the worse for being metaphysical, provided they be founded (which I think they are) in right reasoning: but they are of a nature too wide to be brought under our survey, and it is often difficult to apply them in the detail. Our speculations, therefore, are perhaps better employed when they confine themselves within a narrower circle.

The observations which follow are of this more limited, but more determinate, kind.

Of *bodily pain*, the principal observation, no doubt, is that which we have already made and already dwelt upon, viz. "that it is seldom the object of contrivance; that when it is so, the contrivance rests ultimately in good."

To which, however, may be added, that the annexing of pain to the means of destruction is a salutary provision, inasmuch as it teaches vigilance and caution; both gives notice of danger and excites those endeavours which may be necessary to preservation. The evil consequence, which sometimes arises from the want of that timely intimation of danger which pain gives, is known to the inhabitants of cold countries by the example of frost-bitten limbs. I have conversed with patients who have lost

toes and fingers by this cause. They have in general told me, that they were totally unconscious of any local uneasiness at the time. Some I have heard declare that, whilst they were about their employment, neither their situation, nor the state of the air was unpleasant. They felt no pain; they suspected no mischief; till, by the application of warmth, they discovered, too late, the fatal injury which some of their extremities had suffered. I say that this shows the use of pain, and that we stand in need of such a monitor. In truth we rarely pass an hour without being reminded of the value of pain to admonish us of impending mischief, and to induce us to adopt measures for its relief when inflicted. The senses—the eye in particular—are thus beholden: when deprived of its sensitiveness, this optical instrument is soon spoiled by exposure, for it is no longer swept by the ever-active eyelid to moisten and cleanse it. In like manner are the air-passages protected by the acute sensitiveness of the nostrils and of the upper opening of the larynx: sneezing or spasmodic cough is excited to eject any extraneous matter or intruding particle of food. Attention to the wants of nature are also thus solicited.

It is probable that pain is not experienced

where it is not needed; that, the lower we descend in the scale of creation, there is less sensitiveness to external influences which cause pain in higher organizations.

In many instances no good purpose could be subserved of warning, as in more highly organized beings; thus, insects and crustaceous animals seem to suffer mutilation without apparent pain. The lobster, as already noticed, voluntarily separates and throws off a limb. This inference from observation is supported by the comparative anatomy of the nervous system, and is certainly more consistent with our views of the goodness and benevolence of the Deity. I believe also, that the use of pain extends further than we suppose, or can now trace; that to disagreeable sensations we and all animals owe, or have owed, many habits of action which are salutary, but which are become so familiar, as not easily to be referred to their origin.

PAIN also itself is not without its *alleviations*. It may be violent and frequent; but it is seldom both violent and long continued: and its pauses and intermissions become positive pleasures. It has the power of shedding a satisfaction over intervals of ease, which I believe few enjoyments exceed. A man resting from a fit of the stone

or gout is, for the time, in possession of feelings which undisturbed health cannot impart. They may be dearly bought, but still they are to be set against the price. And indeed it depends upon the duration and urgency of the pain, whether they be dearly bought or not. I am far from being sure, that a man is not a gainer by suffering a moderate interruption of bodily ease for a couple of hours out of the four-and-twenty. Two very common observations favour this opinion : one is, that remissions of pain call forth, from those who experience them, stronger expressions of satisfaction and of gratitude towards both the author and the instruments of their relief, than are excited by advantages of any other kind : the second is, that the spirits of sick men do not sink in proportion to the acuteness of their sufferings ; but rather appear to be roused and supported, not by pain but by the high degree of comfort which they derive from its cessation, or even its subsidency, whenever that occurs ; and which they taste with a relish that diffuses some portion of mental complacency over the whole of that mixed state of sensations in which disease has placed them.

In connexion with bodily pain may be considered bodily *disease*, whether painful or not. Few diseases are fatal. I have before me the

---

account of a dispensary in the neighbourhood, which states six years' experience as follows :—

|                    |      |
|--------------------|------|
| Admitted . . . . . | 6420 |
| Cured . . . . .    | 5476 |
| Dead . . . . .     | 234  |

And this I suppose nearly to agree with what other similar institutions exhibit. Now, in all these cases, some disorder must have been felt, or the patients would not have applied for a remedy ; yet we see how large a proportion of the maladies, which were brought forward, have either yielded to proper treatment, or, what is more probable, ceased of their own accord. We owe these frequent recoveries, and, where recovery does not take place, this patience of the human constitution under many of the distempers by which it is visited, to two benefactions of our nature. One is, that she works within certain limits ; allows of a certain latitude within which health may be preserved, and within the confines of which it only suffers a graduated diminution. Different quantities of food, different degrees of exercise, different portions of sleep, different states of the atmosphere, are compatible with the possession of health. So likewise is it with the secretions and excretions, with many internal functions of the body, and with the state, probably, of most of its internal

organs. They may vary considerably, not only without destroying life, but without occasioning any high degree of inconvenience. The other property of our nature, to which we are still more beholden, is its constant endeavour to restore itself, when disordered, to its regular course. For that which we popularly call “disease” is usually the effort of nature to expel a poison from the system, as in various eruptive fevers. The struggle may terminate fatally; but without it, the poison must destroy life if not eliminated.

Of *mortal* diseases the great use is to reconcile us to death. The horror of death proves the value of life. But it is in the power of disease to abate, or even extinguish, this horror; which it does in a wonderful manner, and oftentimes by a mild and imperceptible gradation. Every man who has been placed in a situation to observe it, is surprised with the change which has been wrought in himself, when he compares the view which he entertains of death upon a sick-bed, with the heart-sinking dismay with which he should some time ago have met it in health. There is no similitude between the sensations of a man led to execution, and the calm expiring of a patient at the close of his disease. Death to him is only the last of a long train of changes;

in his progress through which it is possible that he may experience no shocks or sudden transitions.

*Death* itself, as a mode of removal and of succession, is so connected with the whole order of our animal world, that almost everything in that world must be changed, to be able to do without it. It may seem likewise impossible to separate the fear of death from the enjoyment of life, or the perception of that fear from rational natures. Brutes are in a great measure delivered from all anxiety on this account by the inferiority of their faculties ; they seem to be armed with the apprehension of death, or rather of injury, just sufficiently to put them upon the means of preservation, and no further. But would a human being wish to purchase this immunity at the expense of those mental powers which enable him to look forward to the future ?

Death implies *separation* : and the loss of those whom we love must necessarily, so far as we can conceive, be accompanied with pain. To the brute creation, nature seems to have stepped in with some secret provision for their relief, under the rupture of their attachments. In their instincts towards their offspring, and of their offspring to them, I have often been surprised to observe how ardently they love, and how soon

they forget. The pertinacity of human sorrow (upon which time also, at length, lays its softening hand) is probably, therefore, in some manner connected with the qualities of our rational or mortal nature. One thing however is clear, viz. that it is better that we should possess affections, the sources of so many virtues and so many joys, although they be exposed to the incidents of life, as well as the interruptions of mortality, than, by the want of them, be reduced to a state of selfishness, apathy, and quietism.

Of other external evils (still confining ourselves to what are called physical or natural evils), a considerable part come within the scope of the following observation:—The great principle of human satisfaction is *engagement*. It is a most just distinction, which the late Mr. Tucker has dwelt upon so largely in his works, between pleasures in which we are passive, and pleasures in which we are active. And, I believe, every attentive observer of human life will assent to his position, that however grateful the sensations may occasionally be in which we are passive, it is not these, but the latter class of our pleasures, which constitute satisfaction; which supply that regular stream of moderate and miscellaneous enjoyments, in which happiness, as

---

distinguished from voluptuousness, consists. Now for rational occupation, which is, in other words, for the very material of contented existence, there would be no place left, if either the things with which we had to do were absolutely impracticable to our endeavours, or if they were too obedient to our uses. A world, furnished with advantages on one side, and beset with difficulties, wants, and inconveniences on the other, is the proper abode of free, rational, and active natures, being the fittest to stimulate and exercise their faculties. The very *refractoriness* of the objects they have to deal with contributes to this purpose. A world in which nothing depended upon ourselves, however it might have suited an imaginary race of beings, would not have suited mankind. Their skill, prudence, industry; their various arts, and their best attainments, from the application of which they draw, if not their highest, their most permanent gratifications, would be insignificant, if things could be either moulded by our volitions, or, of their own accord, conformed themselves to our views and wishes. Now it is in this refractoriness that we discern the seed and principle of *physical* evil, as far as it arises from that which is external to us.

*Civil* evils, or the evils of civil life, are much

more easily disposed of than physical evils : because they are, in truth, of much less magnitude, and also because they result, by a kind of necessity, not only from the constitution of our nature, but from a part of that constitution which no one would wish to see altered. The case is this : Mankind will in every country *breed up* to a certain point of distress. That point may be different in different countries or ages, according to the established usages of life in each. It will also shift upon the scale, so as to admit of a greater or less number of inhabitants, according as the quantity of provision, which is either produced in the country or supplied to it from other countries, may happen to vary. But there must always be such a point, and the species will always breed up to it. The order of generation proceeds by something like a geometrical progression. The increase of provision, under circumstances even the most advantageous, can only assume the form of an arithmetic series. Whence it follows, that the population will always overtake the provision, will pass beyond the line of plenty, and will continue to increase till checked by the difficulty of procuring subsistence. Such difficulty, therefore, along with its attendant circumstances, *must* be found in every old country : and these circum-

stances constitute what we call poverty, which necessarily imposes labour, servitude, restraint.

It seems impossible to people a country with inhabitants who shall be all easy in circumstances. For suppose the thing to be done, there would be such marrying and giving in marriage amongst them, as would in a few years change the face of affairs entirely; i.e. as would increase the consumption of those articles, which supplied the natural or habitual wants of the country, to such a degree of scarcity, as must leave the greatest part of the inhabitants unable to procure them without toilsome endeavours, or, out of the different kinds of these articles, to procure any kind except that which was most easily produced. And this, in fact, describes the condition of the mass of the community in all countries: a condition unavoidably, as it should seem, resulting from the provision which is made in the human, in common with all animal constitutions, for the perpetuity and multiplication of the species.

It need not however dishearten any endeavours for the public service, to know that population naturally treads upon the heels of improvement. If the condition of a people be meliorated, the consequence will be, either that

the *mean* happiness will be increased, or a greater number partake of it; or, which is most likely to happen, that both effects will take place together. There may be limits fixed by nature to both, but they are limits not yet attained, nor even approached, in any country of the world.

And when we speak of limits at all, we have respect only to provisions for animal wants. There are sources, and means, and auxiliaries, and augmentations of human happiness, communicable without restriction or numbers; as capable of being possessed by a thousand persons as by one. Such are those which flow from a mild, contrasted with a tyrannic, government, whether civil or domestic; those which spring from religion; those which grow out of a sense of security; those which depend upon habits of virtue, sobriety, moderation, order; those, lastly, which are found in the possession of well-directed tastes and desires, compared with the dominion of tormenting, pernicious, contradictory, unsatisfied, and unsatisfiable passions.

The *distinctions* of civil life are apt enough to be regarded as evils, by those who sit under them; but, in my opinion, with very little reason.

In the first place, the advantages which the

---

higher conditions of life are supposed to confer, bear no proportion in value to the advantages which are bestowed by nature. The gifts of nature always surpass the gifts of fortune. How much, for example, is activity better than attendance; beauty than dress; appetite, digestion, and tranquil bowels, than all the studies of cookery, or than the most costly compilation of forced, or far-fetched dainties!

Nature has a strong tendency to equalization. Habit, the instrument of nature, is a great leveller; the familiarity which it induces taking off the edge both of our pleasures and our sufferings. Indulgencies which are habitual keep us in ease, and cannot be carried much further: indeed, by becoming necessary to us, privation of them becomes an evil. Furthermore, the pleasure of acquisition is denied, in great measure, to him whose wants are gratified almost as soon as suggested. So that, with respect to the gratifications of which the senses are capable, the difference is by no means proportionable to the apparatus. Nay, so far as superfluity generates fastidiousness, the difference is on the wrong side.

It is not necessary to contend, that the advantages derived from wealth are none (under due regulation they are certainly considerable), but

that they are not greater than they ought to be. *Money* is the sweetener of human toil ; the substitute for coercion ; the reconciler of labour with liberty. It is, moreover, the stimulant of enterprise in all projects and undertakings, as well as of diligence in the most beneficial arts and employments. Now did affluence, when possessed, contribute nothing to happiness, or nothing beyond the mere supply of necessaries ; and the secret should come to be discovered ; we might be in danger of losing great part of the uses, which are at present derived to us through this important medium. Not only would the tranquillity of social life be put in peril, by the want of a motive to attach men to their private concerns ; but the satisfaction which all men receive from success in their respective occupations, which collectively constitutes the great mass of human comfort, would be done away in its very principle.

With respect to *station*, as it is distinguished from riches, whether it confer authority over others, or be invested with honours which apply solely to sentiment and imagination, the truth is, that which is gained by rising through the ranks of life is not more than sufficient to draw forth the exertions of those who are engaged in the pursuits which lead to advance-

---

ment, and which in general are such as ought to be encouraged. Distinctions of this sort are subjects much more of competition than of enjoyment: and in that competition their use consists. It is not, as hath been rightly observed, by what the *Lord Mayor* feels in his coach, but by what the *apprentice* feels who gazes at him, that the public is served.

As we approach the summits of human greatness, the comparison of good and evil, with respect to personal comfort, becomes still more problematical; even allowing to ambition all its pleasures. The poet asks, “What is grandeur, what is power?” The philosopher answers, “Constraint and plague: *et in maximâ quâque fortundâ minimum licere.*” One very common error misleads the opinion of mankind on this head, viz. that, universally, authority is pleasant, submission painful. In the general course of human affairs, the very reverse of this is nearer to the truth. Command is anxiety, obedience ease. Distinction and an elevated position have, as their associates, care and responsibility.

Artificial distinctions sometimes promote real equality. Whether they be hereditary, or be the homage paid to office, or the respect attached by public opinion to particular professions, they serve to *confront* that grand and unavoidable

distinction which arises from property, and which is most overbearing where there is no other. It is of the nature of property not only to be regularly distributed, but to run into large masses. Public laws should be so constructed as to favour its diffusion as much as they can. But all that can be done by laws consistently with that degree of government of his property which ought to be left to the subject, will not be sufficient to counteract this tendency. There must always therefore be the difference between rich and poor; and this difference will be the more grinding, when no pretension is allowed to be set up against it.

So that the evils, if evils they must be called, which spring either from the necessary subordinations of civil life, or from the distinctions which have, naturally, though not necessarily, grown up in most societies, so long as they are unaccompanied by privileges injurious or oppressive to the rest of the community, are such as may, even by the most depressed ranks, be endured with very little prejudice to their comfort.

The mischiefs of which mankind are the occasion to one another, by their private wickedness and cruelties; by tyrannical exercises of power; by rebellions against just authority; by wars; by national jealousies and competitions operating

to the destruction of countries; or by other instances of misconduct either in individuals or societies, are all to be resolved into the character of man as a *free agent*. Free agency in its very essence contains liability to abuse. Yet, if you deprive man of his free agency, you subvert his nature. You may have order from him and regularity, as you may from the tides or the trade-winds, but you put an end to his moral character, to virtue, to merit, to accountableness, to the use indeed of reason. To which must be added the observation, that even the bad qualities of mankind have an origin in their good ones. The case is this: human passions are either necessary to human welfare, or capable of being made, and in a great majority of instances, in fact, are made, conducive to its happiness. These passions are strong and general; and perhaps would not answer their purpose unless they were so. But strength and generality, when it is expedient that particular circumstances should be respected, become, if left to themselves, excess and misdirection. From which excess and misdirection the vices of mankind (the causes no doubt of much misery) appear to spring. This account, whilst it shows us the principle of vice, shows us, at the same time, the province of reason and of self-government; the want also

of every support which can be procured to either from the aids of religion; and it shows this, without having recourse to any native gratuitous malignity in the human constitution. Mr. Hume, in his posthumous dialogues, asserts indeed of *idleness*, or aversion to labour (which he states to lie at the root of a considerable part of the evils which mankind suffer), that it is simple and merely bad. But how does he distinguish idleness from the love of ease? or is he sure that the love of ease in individuals is not the chief foundation of social tranquillity? It will be found, I believe, to be true, that in every community there is a large class of its members, whose idleness is the best quality about them, being the corrective of other bad ones. If it were possible, in every instance, to give a right determination to industry, we could never have too much of it. But this is not possible, if men are to be free. And without this, nothing would be so dangerous, as an incessant, universal, indefatigable activity. In the civil world, as well as in the material, it is the *vis inertiae* which keeps things in their places.

NATURAL THEOLOGY has ever been pressed with this question; Why, under the regency of a supreme and benevolent Will, should there be,

in the world, so much as there is of the appearance of *chance*?

The question in its whole compass lies beyond our reach: but there are not wanting, as in the origin of evil, answers which seem to have considerable weight in particular cases, and also to embrace a considerable number of cases.

I. There must be *chance* in the midst of design: by which we mean, that events which are not designed necessarily arise from the pursuit of events which are designed. One man travelling to York meets another man travelling to London. Their meeting is by chance, is accidental, and so would be called and reckoned, though the journeys which produced the meeting were both of them undertaken with design and from deliberation. The meeting, though accidental, was nevertheless hypothetically necessary (which is the only sort of necessity that is intelligible): for, if the two journeys were commenced at the time, pursued in the direction, and with the speed in which and with which they were in fact begun and performed, the meeting could not be avoided. There was not therefore the less necessity in it for its being by chance. Again, the encounter might be most unfortunate, though the errands, upon which each party set out upon his journey, were the

most innocent or the most laudable. The by-effect may be unfavourable, without impeachment of the proper purpose, for the sake of which the train, from the operation of which these consequences ensued, was put in motion. Although no cause acts without a good purpose, accidental consequences, like these, may be either good or bad.

II. The *appearance of chance* will always bear a proportion to the ignorance of the observer. The cast of a die as regularly follows the laws of motion, as the going of a watch; yet because we can trace the operation of those laws through the works and movements of the watch, and cannot trace them in the shaking and throwing of the die (though the laws be the same, and prevail equally in both cases), we call the turning up of the number of the die chance, the pointing of the index of the watch machinery, order, or by some name which excludes chance. It is the same in those events which depend upon the will of a free and rational agent. The verdict of a jury, the sentence of a judge, the resolution of an assembly, the issue of a contested election, will have more or less of the appearance of chance, might be more or less the subject of a wager, according as we were less or more acquainted with the reasons which in-

fluenced the deliberation. The difference resides in the information of the observer, and not in the thing itself; which, in all the cases proposed, proceeds from intelligence, from mind, from counsel, from design.

Now when this one cause of the appearance of chance, viz. the ignorance of the observer, comes to be applied to the operations of the Deity, it is easy to foresee how fruitful it must prove of difficulties, and of seeming confusion. It is only to think of the Deity, to perceive what variety of objects, what distance of time, what extent of space and action, His counsels may, or rather must, comprehend. Can it be wondered at, that, of the purposes which dwell in such a mind as this, so small a part should be known to us? It is only necessary, therefore, to bear in our thought, that in proportion to the inadequateness of our information will be the quantity, in the world, of apparent chance.

III. In a great variety of cases, and of cases comprehending numerous subdivisions, it appears, for many reasons, to be better that events rise up by *chance*, or, more properly speaking, with the appearance of chance, than according to any observable rule whatever. This is not seldom the case even in human arrangements.

Each person's place and precedence, in a public meeting, may be determined by *lot*. Work and labour may be *allotted*. Tasks and burdens may be *allotted* :—

Operumque laborem  
Partibus æquabat justis, aut sorte trahebat.

Military service and station may be *allotted*. The distribution of provision may be made by *lot*, as it is in a sailor's mess ; in some cases also, the distribution of favours may be made by *lot*. In all these cases it seems to be acknowledged, that there are advantages in permitting events to chance, superior to those which would or could arise from regulation. In all these cases, also, though events rise up in the way of chance, it is by appointment that they do so.

In other events, and such as are independent of human will, the reasons for this preference of uncertainty to rule appear to be still stronger. For example, it seems to be expedient that the period of human life should be *uncertain*. Did mortality follow any fixed rule, it would produce a security in those that were at a distance from it, which would lead to the greatest disorders ; and a horror in those who approach it, similar to that which a condemned prisoner feels on the night before his execution : but that death be uncertain, the young must sometimes die, as

---

well as the old. Also were deaths never *sudden*, they who are in health would be too confident of life. The strong and the active, who want most to be warned and checked, would live without apprehension or restraint. On the other hand, were sudden deaths very frequent, the sense of constant jeopardy would interfere too much with the degree of ease and enjoyment intended for us ; and human life be too precarious for the business and interests which belong to it. There could not be dependence either upon our own lives, or the lives of those with whom we are connected, sufficient to carry on the regular offices of human society. The manner, therefore, in which death is made to occur, conduces to the purposes of admonition, without overthrowing the necessary stability of human affairs.

*Disease* being the forerunner of death, there is the same reason for its attacks coming upon us under the appearance of chance, as there is for uncertainty in the time of death itself.

The *seasons* are a mixture of regularity and chance. They are regular enough to authorize expectation, whilst their being in a considerable degree irregular induces, on the part of the cultivators of the soil, a necessity for personal attendance, for activity, vigilance, precaution.

It is this necessity which creates farmers ; which divides the profit of the soil between the owner and the occupier ; which, by requiring expedients, by increasing employment, and by rewarding expenditure, promotes agricultural arts and agricultural life, of all modes of life the best, being the most conducive to health, to virtue, to enjoyment. I believe it to be found in fact, that where the soil is the most fruitful, and the seasons the most constant, there the condition of the cultivators of the earth is the most depressed. Uncertainty, therefore, has its use even to those who sometimes complain of it the most. Seasons of scarcity themselves are not without their advantages. They call forth new exertions ; they set contrivance and ingenuity at work ; they give birth to improvements in agriculture and economy ; they promote the investigation and management of public resources.

Again ; there are strong intelligible reasons, why there should exist in human society great disparity of *wealth* and *station* ; not only as these things are acquired in different degrees, but at the first setting out of life. In order, for instance, to answer the various demands of civil life, there ought to be amongst the members of every civil society a diversity of educa-

---

tion, which can only belong to an original diversity of circumstances. As this sort of disparity, which ought to take place from the beginning of life, must, *ex hypothesi*, be previous to the merit or demerit of the persons upon whom it falls, can it be better disposed of than by chance? *Parentage* is that sort of chance: yet it is the commanding circumstance which in general fixes each man's place in civil life, along with everything which appertains to its distinctions. It may be the result of a beneficial rule, that the fortunes or honours of the father devolve upon the son; and, as it should seem, of a still more necessary rule, that the low or laborious condition of the parent be communicated to his family; but with respect to the successor himself, it is the drawing of a ticket in a lottery. Inequalities therefore of fortune, at least the greatest part of them, viz. those which attend us from our birth and depend upon our birth, may be left, as they are left, to *chance*, without any just cause for questioning the regency of a supreme Disposer of events.

But not only the donation, when by the necessity of the case they must be gifts, but even the *acquirability* of civil advantages ought, perhaps, in a considerable degree, to lie at the mercy of chance. Some would have all the

virtuous rich, or at least removed from the evils of poverty, without perceiving, I suppose, the consequence, that all the poor must be wicked. And how such a society could be kept in subjection to government has not been shown : for the poor, that is, they who seek their subsistence by constant manual labour, must still form the mass of the community ; otherwise the necessary labour of life could not be carried on ; the work would not be done, which the wants of mankind in a state of civilization, and still more in a state of refinement, require to be done.

It appears to be also true, that the exigencies of social life call not only for an original diversity of *external* circumstances, but for a mixture of different faculties, tastes, and tempers. Activity and contemplation, restlessness and quiet, courage and timidity, ambition and contentedness, not to say even indolence and dulness, are all wanted in the world, all conduce to the well going on of human affairs, just as the rudder, the sails and the ballast of a ship, all perform their part in the navigation. Now, since these characters require for their foundation different original talents, different dispositions, perhaps also different bodily constitutions ; and since likewise it is apparently expedient, that they be promiscuously scattered amongst the different

classes of society : can the distribution of talents, dispositions, and the constitutions upon which they depend, be better made than by *chance* ?

The *opposites* of apparent chance are constancy and sensible interposition ; every degree of *secret* direction being consistent with it. Now of *constancy*, or of fixed and known rules, we have seen in some cases the inapplicability : and inconveniences which we do not see, might attend their application in other cases.

Of *sensible* interposition we may be permitted to remark, that a Providence, always and certainly distinguishable, would be neither more nor less than miracles rendered frequent and common. It is difficult to judge of the state into which this would throw us. It is enough to say, that it would cast us upon a quite different dispensation from that under which we live. It would be a total and radical change. And the change would deeply affect, or perhaps subvert, the whole conduct of human affairs. I can readily believe that, other circumstances being adapted to it, such a state might be better than our present state. It may be the state of other beings ; it may be ours hereafter. But the question with which we are now concerned is, how far it would be consistent with our condition, supposing it in other respects to remain

as it is? And in this question there seem to be reasons of great moment on the negative side. For instance, so long as bodily labour continues, on so many accounts, to be necessary for the bulk of mankind, any dependency upon supernatural aid, by unfixing those motives which promote exertion, or by relaxing those habits which engender patient industry, might introduce negligence, inactivity and disorder, into the most useful occupations of human life; and thereby deteriorate the condition of human life itself.

As moral agents we should experience a still greater alteration; of which more will be said under the next article.

Although therefore the Deity, who possesses the power of winding and turning, as He pleases, the course of causes which issue from Himself, do in fact interpose to alter and intercept effects, which without such interposition would have taken place; yet it is by no means incredible that His Providence, which always rests upon final good, may have made a *reserve* with respect to the manifestation of His interference a part of the very plan which He has appointed for our terrestrial existence, and a part conformable with, or in some sort required by, other parts of the same plan. It is at any rate evident, that a large and ample province remains

for the exercise of Providence, without its being naturally perceptible by us; because obscurity, when applied to the interruption of laws, bears a necessary proportion to the imperfection of our knowledge when applied to the laws themselves, or rather to the effects which these laws, under their various and incalculable combinations, would of their own accord produce. And if it be said that the doctrine of Divine Providence, by reason of the ambiguity under which its exertions present themselves, can be attended with no *practical* influence upon our conduct; that, although we believe ever so firmly that there is a Providence, we must prepare, and provide, and act, as if there were none; I answer, that this is admitted: and that we further allege, that so to prepare, and so to provide, is consistent with the most perfect assurance of the reality of a Providence: and not only so, but that it is probably one advantage of the present state of our information, that our provisions and preparations are not disturbed by it. Or if it be still asked, of what use at all then is the doctrine, if it neither alter our measures nor regulate our conduct? I answer again, that it is of the greatest use, but that it is a doctrine of sentiment and piety, not (immediately at least) of action or conduct;

that it applies to the consolation of men's minds, to their devotions, to the excitement of gratitude, the support of patience, the keeping alive and the strengthening of every motive for endeavouring to please our Maker; and that these are great uses.

OF ALL VIEWS under which human life has ever been considered, the most reasonable in my judgment is that which regards it as a state of *probation*. If the course of the world was separated from the contrivances of nature, I do not know that it would be necessary to look for any other account of it than what, if it may be called an account, is contained in the answer, that events rise up by chance. But since the contrivances of nature decidedly evince *intention*; and since the course of the world and the contrivances of nature have the same author; we are, by the force of this connexion, led to believe, that the appearance under which events take place is reconcilable with the supposition of design on the part of the Deity. It is enough that they be reconcilable with this supposition; and it is undoubtedly true, that they may be reconcilable, though we cannot reconcile them. The mind, however, which contemplates the works of nature, and in those works sees so much of means directed to ends, of beneficial

effects brought about by wise expedients, of concerted trains of causes terminating in the happiest results ; so much, in a word, of counsel, intention, and benevolence : a mind, I say, drawn into the habit of thought which these observations excite, can hardly turn its view to the condition of our own species, without endeavouring to suggest to itself some purpose, some design, for which the state in which we are placed is fitted, and which it is made to serve. Now we assert the most probable supposition to be, that it is a state of moral probation ; and that many things in it suit with this hypothesis, which suit no other. It is not a state of unmixed happiness, or of happiness simply : it is not a state of designed misery, or of misery simply : it is not a state of retribution : it is not a state of punishment. It suits with none of these suppositions. It accords much better with the idea of its being a condition calculated for the production, exercise, and improvement of moral qualities, with a view to a future state, in which these qualities, after being so produced, exercised, and improved, may, by a new and more favouring constitution of things, receive their reward, or become their own. If it be said, that this is to enter upon a religious rather than a philosophical consideration, I answer,

that the name of Religion ought to form no objection, if it shall turn out to be the case; that the more religious our views are, the more probability they contain. The degree of beneficence, of benevolent intention, and of power, exercised in the construction of sensitive beings, goes strongly in favour, not only of a creative, but of a continuing care, that is, of a ruling Providence. The degree of chance, which appears to prevail in the world, requires to be reconciled with this hypothesis. Now it is one thing to maintain the doctrine of Providence along with that of a future state, and another thing without it. In my opinion, the two doctrines must stand or fall together. For although more of this apparent chance may perhaps, upon other principles, be accounted for, than is generally supposed, yet a future state alone rectifies all disorders: and if it can be shown, that the appearance of disorder is consistent with the uses of life as a *preparatory* state, or that in some respects it promotes these uses, then, so far as this hypothesis may be accepted, the ground of the difficulty is done away.

In the wide scale of human condition, there is not perhaps one of its manifold diversities which does not bear upon the design here suggested. Virtue is infinitely various. There is

no situation in which a rational being is placed, from that of the best instructed Christian down to the condition of the rudest barbarian, which affords not room for moral agency; for the acquisition, exercise and display of voluntary qualities, good and bad. Health and sickness, enjoyment and suffering, riches and poverty, knowledge and ignorance, power and subjection, liberty and bondage, civilization and barbarity, have all their offices and duties, all serve for the *formation* of character: for when we speak of a state of trial, it must be remembered that characters are not only tried, or proved, or detected, but that they are generated also, and *formed*, by circumstances. The best dispositions may subsist under the most depressed, the most afflicted fortunes. An oppressed slave, who, amidst his wrongs, retains his benevolence, I for my part look upon as amongst the foremost of human candidates for the rewards of virtue. The kind master of such a slave, that is, he, who in the exercise of an inordinate authority, postpones in any degree his own interest to his slave's comfort, is likewise a meritorious character: but still he is inferior to his slave. All however which I contend for is, that these destinies, opposite as they may be in every other view, are both *trials*; and equally such. The

observation may be applied to every other condition ; to the whole range of the scale, not excepting even its lowest extremity. *Savages* appear to us all alike ; but it is owing to the distance at which we view savage life, that we perceive in it no discrimination of character. I make no doubt but that moral qualities, both good and bad, are called into action as much, and that they subsist in as great variety in these inartificial societies, as they are, or do, in polished life. Certain at least it is, that the good and ill treatment which each individual meets with depends more upon the choice and voluntary conduct of those about him, than it does or ought to do, under regular civil institutions and the coercion of public laws. So again, to turn our eyes to the other end of the scale, namely, that part of it which is occupied by mankind enjoying the benefits of learning, together with the lights of revelation, there also, the advantage is all along *probationary*. Christianity itself, I mean the revelation of Christianity, is not only a blessing but a trial. It is one of the diversified means by which the character is exercised : and they who require of Christianity, that the revelation of it should be universal, may possibly be found to require that one species of probation should be adopted,

---

if not to the exclusion of others, at least to the narrowing of that variety which the wisdom of the Deity hath appointed to this part of His moral economy.<sup>1</sup>

Now if this supposition be well founded; that is, if it be true that our ultimate or our most permanent happiness will depend, not upon the temporary condition into which we are cast, but upon our behaviour in it; then is it a much more fit subject of *chance* than we usually allow or apprehend it to be, in what manner the variety of external circumstances, which subsist in the human world, is distributed amongst the individuals of the species. “This life being a state of probation, it is immaterial,” says Rousseau, “what kind of trials we experience in it, provided they produce their effects.” Of two agents who stand indifferent to the moral Governor of the universe, one may be exercised by riches, the other by poverty. The

<sup>1</sup> The reader will observe, that I speak of the revelation of Christianity as distinct from Christianity itself. The dispensation may already be universal. That part of mankind which never heard of CHRIST’s name may nevertheless be redeemed; that is, be placed in a better condition, with respect to their future state, by His intervention; may be the objects of His benignity and intercession, as well as of the propitiatory virtue of His passion. But this is not “natural theology;” therefore I will not dwell longer upon it.

treatment of these two shall appear to be very opposite, whilst in truth it is the same: for though in many respects there be great disparity between the conditions assigned, in one main article there may be none, viz. in that they are like trials; have both their duties and temptations, not less arduous or less dangerous in one case than the other; so that if the final award follow the character, the original distribution of the circumstances under which that character is formed may be defended upon principles not only of justice but of equality. What hinders, therefore, but that mankind may draw lots for their condition? They take their portion of faculties and opportunities, as any unknown cause, or concourse of causes, or as causes acting for other purposes, may happen to set them out; but the event is governed by that which depends upon themselves, the application of what they have received. In dividing the talents no rule was observed; none was necessary: in rewarding the use of them, that of the most correct justice. The chief difference at last appears to be, that the right use of more talents, i.e. of a greater trust, will be more highly rewarded, than the right use of fewer talents, i.e. of a less trust. And since, for other purposes, it is expedient that there be an

inequality of concredited talents here, as well probably as an inequality of conditions hereafter, though all remuneratory, can any rule, adapted to that inequality, be more agreeable, even to our apprehensions of distributive justice, than this is?

We have said that the appearance of *casualty*, which attends the occurrences and events of life, not only does not interfere with its uses, as a state of probation, but that it promotes these uses.

*Passive* virtues, of all others the severest and the most sublime; of all others perhaps the most acceptable to the Deity; would, it is evident, be excluded from a constitution in which happiness and misery regularly followed virtue and vice. Patience and composure under distress, affliction, and pain; a steadfast keeping up of our confidence in God, and of our reliance upon His final goodness, at the time when everything present is adverse and discouraging; and (what is no less difficult to retain) a cordial desire for the happiness of others, even when we are deprived of our own: these dispositions, which constitute, perhaps, the perfection of our moral nature, would not have found their proper office and object in a state of avowed retribution; and in which, consequently, endurance of evil would be only submission to punishment.

Again : one man's sufferings may be another man's trial. The family of a sick parent is a school of filial piety. The charities of domestic life, and not only these, but all the social virtues, are called out by distress. But then, misery, to be the proper object of mitigation, or of that benevolence which endeavours to relieve, must be really or apparently casual. It is upon such sufferings alone that benevolence can operate. For were there no evils in the world, but what were punishments, properly and intelligibly such, benevolence would only stand in the way of justice. Such evils, consistently with the administration of moral government, could not be prevented or alleviated, that is to say, could not be remitted in whole or in part, except by the authority which inflicted them, or by an appellate or superior authority. This consideration, which is founded in our most acknowledged apprehensions of the nature of penal justice, may possess its weight in the Divine councils. Virtue perhaps is the greatest of all ends. In human beings, relative virtues form a large part of the whole. Now relative virtue presupposes not only the existence of evil, without which it could have no object, no material to work upon, but that evils be, apparently at least, *misfortunes* ; that is, the effects of apparent chance. It may

be in pursuance, therefore, and in furtherance of the same scheme of probation, that the evils of life are made so to present themselves.

I have already observed, that, when we let in religious considerations, we often let in light upon the difficulties of nature. So in the fact now to be accounted for, the *degree* of happiness, which we usually enjoy in this life, may be better suited to a state of trial and probation, than a greater degree would be. The truth is, we are rather too much delighted with the world, than too little. Imperfect, broken and precarious as our pleasures are, they are more than sufficient to attach us to the eager pursuit of them. A regard to a *future* state can hardly keep its place as it is. If we were designed therefore to be influenced by that regard, might not a more indulgent system, a higher or more uninterrupted state of gratification, have interfered with the design? At least it seems expedient that mankind should be susceptible of this influence, when presented to them: that the condition of the world should not be such as to exclude its operation, or even to weaken it more than it does. In a religious view (however we may complain of them in every other), privation, disappointment, and satiety, are not without the most salutary tendencies.

## CHAPTER XXVII.

## CONCLUSION.

IN all cases, wherein the mind feels itself in danger of being confounded by variety, it is sure to rest upon a few strong points, or perhaps upon a single instance. Amongst a multitude of proofs, it is *one* that does the business. If we observe, in any argument, that hardly two minds fix upon the same instance, the diversity of choice shows the strength of the argument, because it shows the number and competition of the examples. There is no subject in which the tendency to dwell upon select or single topics is so usual, because there is no subject of which, in its full extent, the latitude is so great, as that of natural history applied to the proof of an intelligent Creator. For my part, I take my stand in human anatomy; and the examples of mechanism I should be apt to draw out from the copious catalogue which it supplies, are the

---

pivot upon which the head turns, the ligament within the socket of the hip-joint, the pulley or trochlear muscles of the eye, the epiglottis, the bands which tie down the tendons of the wrist and instep, the slit or perforated tendons at the hands and feet, the attachment of the intestines to the mesentery, the course of the chyle into the blood, and the constitution of the sexes as extended throughout the whole of the animal creation. To these instances the reader's memory will go back, as they are severally set forth in their places ; there is not one of the number which I do not think decisive ; not one which is not strictly mechanical ; nor have I read or heard of any solution of these appearances, which, in the smallest degree, shakes the conclusion that we build upon them.

But, of the greatest part of those, who, either in this book or any other, read arguments to prove the existence of a God, it will be said, that they leave off only where they began ; that they were never ignorant of this great truth, never doubted of it ; that it does not therefore appear, what is gained by researches from which no new opinion is learnt, and upon the subject of which no proofs were wanted. Now, I answer that, by *investigation*, the following points are always gained, in favour of doctrines

---

even the most generally acknowledged (supposing them to be true), viz. stability and impression. Occasions will arise to try the firmness of our most habitual opinions. And upon these occasions, it is a matter of incalculable use to feel our foundation ; to find a support in argument for what we had taken up upon authority. In the present case, the arguments upon which the conclusion rests are exactly such as a truth of universal concern ought to rest upon. “They are sufficiently open to the views and capacities of the unlearned, at the same time that they acquire new strength and lustre from the discoveries of the learned.” If they had been altogether abstruse and recondite, they would not have found their way to the understandings of the mass of mankind ; if they had been merely popular, they might have wanted solidity.

But, secondly, what is gained by research in the stability of our conclusion, is also gained from it in *impression*. Physicians tell us, that there is a great deal of difference between taking a medicine, and the medicine getting into the constitution. A difference, not unlike this, obtains with respect to those great moral propositions, which ought to form the directing principles of human conduct. It is

one thing to assent to a proposition of this sort ; another, and a very different thing, to have properly imbibed its influence. I take the case to be this : perhaps almost every man living has a particular train of thought, into which his mind glides and falls, when at leisure from the impressions and ideas that occasionally excite it ; perhaps, also, the train of thought here spoken of, more than any other thing, determines the character. It is of the utmost consequence, therefore, that this property of our constitution be well regulated. Now it is by frequent or continued meditation upon a subject, by placing a subject in different points of view, by induction of particulars, by variety of examples, by applying principles to the solution of phenomena, by dwelling upon proofs and consequences, that mental exercise is drawn into any particular channel. It is by these means, at least, that we have any power over it. The train of spontaneous thought, and the choice of that train, may be directed to different ends, and may appear to be more or less judiciously fixed, according to the purpose in respect of which we consider it : but, in a *moral view*, I shall not, I believe, be contradicted when I say that, if one train of thinking be more desirable than another, it is that which

regards the phenomena of nature with a constant reference to a supreme intelligent Author. To have made this the ruling, the habitual sentiment of our minds, is to have laid the foundation of everything which is religious. The world thenceforth becomes a temple, and life itself one continued act of adoration. The change is no less than this, that, whereas formerly God was seldom in our thoughts, we can now scarcely look upon anything without perceiving its relation to Him. Every organized natural body, in the provisions which it contains for its sustentation and propagation, testifies a care, on the part of the Creator, expressly directed to these purposes. We are on all sides surrounded by such bodies; examined in their parts, wonderfully curious; compared with one another, no less wonderfully diversified. So that the mind, as well as the eye, may either expatiate in variety and multitude, or fix itself down to the investigation of particular divisions of the science. And in either case it will rise up from its occupation, possessed by the subject in a very different manner, and with a very different degree of influence, from what a more assent to any verbal proposition which can be formed concerning the existence of the Deity, at least that merely complying

assent with which those about us are satisfied, and with which we are too apt to satisfy ourselves, will or can produce upon the thoughts. More especially may this difference be perceived, in the degree of admiration and of awe with which the Divinity is regarded, when represented to the understanding by its own remarks, its own reflections and its own reasonings, compared with what is excited by any language that can be used by others. The works of nature want only to be contemplated. When contemplated, they have everything in them which can astonish by their greatness: for, of the vast scale of operation, through which our discoveries carry us, at one end we see an intelligent Power arranging planetary systems, fixing, for instance, the trajectory of *Saturn*, or constructing a ring of two hundred thousand miles diameter, to surround his body, and be suspended like a magnificent arch over the heads of his inhabitants; and, at the other, bending a hooked tooth, concerting and providing an appropriate mechanism for the clasping and reclasping of the filaments of the feather of the humming-bird. We have proof, not only of both these works proceeding from an intelligent agent, but of their proceeding from the same agent; for, in the first place, we can trace an

identity of plan, a connexion of system, from Saturn to our own globe: and when arrived upon our globe, we can, in the second place, pursue the connexion through all the organized, especially the animated, bodies which it supports. We can observe marks of a common relation, as well to one another, as to the elements of which their habitation is composed. Therefore one mind hath planned, or at least hath prescribed, a general plan for all these productions. One Being has been concerned in all.

Under this stupendous Being we live. Our happiness, our existence, is in His hands. All we expect must come from Him. Nor ought we to feel our situation insecure. In every nature, and in every portion of nature, which we can descry, we find attention bestowed upon even the minutest parts. The hinges in the wings of an *earwig*, and the joints of its antennæ, are as highly wrought, as if the Creator had nothing else to finish. We see no signs of diminution of care by multiplicity of objects, or of distraction of thought by variety. We have no reason to fear, therefore, our being forgotten, or overlooked, or neglected.

The existence and character of the Deity, is, in every view, the most interesting of all human speculations. In none, however, is it more so,

than as it facilitates the belief of the fundamental articles of *Revelation*. It is a step to have it proved, that there must be something in the world more than what we see. It is a further step to know that, amongst the invisible things of nature, there must be an intelligent mind concerned in its production, order and support. These points being assured to us by Natural Theology, we may well leave to Revelation the disclosure of many particulars, which our researches cannot reach, respecting either the nature of this Being as the original cause of all things, or His character and designs as a moral Governor ; and not only so, but the more full confirmation of other particulars, of which, though they do not lie altogether beyond our reasonings and our probabilities, the certainty is by no means equal to the importance. The true theist will be the first to listen to *any* credible communication of Divine knowledge. Nothing which he has learned from Natural Theology will diminish his desire of further instruction or his disposition to receive it with humility and thankfulness. He wishes for light : he rejoices in light. His inward veneration of this great Being will incline him to attend, with the utmost seriousness, not only to all that can be discovered concerning Him by

researches into nature, but to all that is taught by a revelation, which gives reasonable proof of having proceeded from Him.

But, above every other article of revealed religion, does the anterior belief of a Deity bear with the strongest force upon that grand point, which gives indeed interest and importance to all the rest,—the resurrection of the human dead. The thing might appear hopeless, did we not see a power at work adequate to the effect, a power under the guidance of an intelligent will, and a power penetrating the inmost recesses of all substance. I am far from justifying the opinion of those, who “thought it a thing incredible, that God should raise the dead :” but I admit that it is first necessary to be persuaded that there *is* a God so do so. This being thoroughly settled in our minds, there seems to be nothing in this process (concealed as we confess it to be) which need to shock our belief. They who have taken up the opinion, that the acts of the human mind depend upon *organization*, that the mind itself indeed consists in organization, are supposed to find a great difficulty than others do, in admitting a transition by death to a new state of sentient existence, because the old organization is apparently dissolved. But I do not see that

any impracticability need be apprehended even by these; or that the change, even upon their hypothesis, is far removed from the analogy of some other operations, which we knew with certainty that the Deity is carrying on. In the ordinary derivation of plants and animals from one another, a particle, in many cases, minuter than all assignable, all conceivable dimension; an aura, an effluvium, an infinitesimal; determines the organization of a future body: does no less than fix, whether that which is about to be produced shall be a vegetable, a merely sentient, or a rational being; an oak, a frog, or a philosopher; makes all these differences; gives to the future body its qualities, and nature, and species. And this particle, from which springs, and by which is determined, a whole future nature, itself proceeds from, and owes its constitution to, a prior body: nevertheless, which is seen in plants most decisively, the incepted organization, though formed within, and through, and by a preceding organization, is not corrupted by its corruption, or destroyed by its dissolution: but, on the contrary, is sometimes extricated and developed by those very causes; survives and comes into action, when the purpose for which it was prepared requires its use. Now an economy which nature has adopted,

when the purpose was to transfer an organization from one individual to another, may have something analogous to it, when the purpose is to transmit an organization from one state of being to another state: and they who found thought in organization, may see something in this analogy applicable to their difficulties; for, whatever can transmit a similarity of organization will answer their purpose, because, according even to their own theory, it may be the vehicle of consciousness, and because consciousness carries identity and individuality along with it through all changes of form or of visible qualities. In the most general case, that, as we have said, of the derivation of plants and animals from one another, the latent organization is either itself similar to the old organization, or has the power of communicating to new matter the old organic form. But it is not restricted to this rule. There are other cases, especially in the progress of insect life, in which the dormant organization does not much resemble that which encloses it, and still less suits with the situation in which the enclosing body is placed, but suits with a different situation to which it is destined. In the larva of the libellula, which lives constantly, and has still long to live, under water, are

described the wings of a fly, which two years afterwards is to mount into the air. Is there nothing in this analogy? It serves at least to show that, even in the observable course of nature, organizations are formed one beneath another; and, amongst a thousand other instances, it shows completely that the Deity can mould and fashion the parts of material nature, so as to fulfil any purpose whatever which He is pleased to appoint.

They who refer the operations of mind to a substance totally and essentially different from matter (as most certainly these operations, though affected by material causes, hold very little affinity to any properties of matter with which we are acquainted), adopt perhaps a juster reasoning and a better philosophy; and by these the considerations above suggested are not wanted, at least in the same *dégré*e. But to such as find, which some persons do find, an insuperable difficulty in shaking off an adherence to those analogies, which the corporeal world is continually suggesting to their thoughts; to such, I say, every consideration will be a relief, which manifests the extent of that intelligent power which is acting in nature, the fruitfulness of its resources, the variety, and aptness, and success of its means; most especially every

consideration which tends to show that, in the translation of a conscious existence, there is not, even in their own way of regarding it, anything greatly beyond, or totally unlike, what takes place in such parts (probably small parts) of the order of nature, as are accessible to our observation.

Again; if there be those who think that the contractedness and debility of the human faculties, in our present state, seem ill to accord with the high destinies which the expectations of religion point out to us, I would only ask them whether any one, who saw a child two hours after its birth, could suppose that it would ever come to understand *fluxions*;<sup>1</sup> who then shall say, what farther amplification of intellectual powers, what accession of knowledge, what advance and improvement, the rational faculty, be its constitution what it will, may not admit of, when placed amidst new objects, and endowed with a sensorium adapted, as it undoubtedly will be, and as our present senses are, to the perception of those substances, and of those properties of things, with which our concern may lie?

Upon the whole; in everything which respects this awful, but, as we trust, glorious

<sup>1</sup> See Search's Light of Nature, *passim*.

---

change, we have a wise and powerful Being (the Author, in nature, of infinitely various expedients for infinitely various ends) upon whom to rely for the choice and appointment of means, adequate to the execution of any plan which His goodness or His justice may have formed, for the moral and accountable part of His terrestrial creation. That great office rests with *Him*: be it *ours* to hope and to prepare, under a firm and settled persuasion that, living and dying, we are His; that life is passed in His constant presence, that death resigns us to His merciful disposal.

THE END.
